Safety Guidelines

The beginning of the Users Guide for GPIB Power Modules Series 661xxA has a Safety Summary page. Be sure you are familiar with the information on that page before programming the power module for operation from a controller.

Printing History

The current edition of this guide is indicated below. Reprints of this guide containing minor corrections and updates may have the same printing date. New editions are identified by a new printing date and, in some cases, by a new part number. A new edition incorporates all new or corrected material since the previous edition. Changes to the guide occurring between editions are covered by change sheets shipped with the guide.

Edition 1........ October, 1991
Edition 2........ February, 1992
Update........... August, 1992
Update........... February, 1993
Edition 3........ September, 1997
Update........... April, 2000

Introduction

About This Guide

You will find the following information in the rest of this guide:

Chapter 2 Introduction to SCPI messages structure, syntax, and data formats. Examples of SCPI programs.
Chapter 3 Dictionary of SCPI commands. Table of module programming parameters.
Chapter 4 Description of the status registers.
Chapter 5 Description of synchronizing outputs with triggers and lists.
Chapter 6 Error messages.
Appendix A SCPI conformance information.
Appendix B Application programs that illustrate features of the power module.

Note Instructions for the Agilent 60001A MPS Keyboard are in the User’s Guide supplied with each module.

Documentation Summary

The following related documents shipped with the system have information helpful to programming the power module:

- **Mainframe User’s Guide.** Information on the GPIB address switch, trigger connections, fault (FLT) and remote inhibit (INH) connections.
- **Module User’s Guide.** Includes specifications and supplemental characteristics, use of the module configuration switch, device related error messages, calibration procedures and use of the MPS keyboard.

External References

**SCPI References**
The following documents will assist you with programming in SCPI:

- **Beginner’s Guide to SCPI.** Part No. H2325-90001. Highly recommended for anyone who has not had previous experience programming with SCPI.
- **Tutorial Description of the GPIB.** Part No. 5952-0156. Highly recommended for those not familiar with the IEEE 488.1 and 488.2 standards.

To obtain a copy of the above documents, contact your local Agilent Technologies Sales and Support Office.

**GPIB References**
The most important GPIB documents are your controller programming manuals - GW BASIC, GPIB Command Library for MS DOS, etc. Refer to these for all non-SCPI commands (for example: Local Lockout).

The following are two formal documents concerning the GPIB interface:

- **ANSI/IEEE Std. 488.1-1987 IEEE Standard Digital Interface for Programmable Instrumentation.** Defines the technical details of the GPIB interface. While much of the information is beyond the need of most programmers, it can serve to clarify terms used in this guide and in related documents.
- **ANSI/IEEE Std. 488.2-1987 IEEE Standard Codes, Formats, Protocols, and Common Commands.** Recommended as a reference only if you intend to do fairly sophisticated programming. Helpful for finding precise definitions of certain types of SCPI message formats, data types, or common commands.

The above two documents are available from the IEEE (Institute of Electrical and Electronics Engineers), 345 East 47th Street, New York, NY 10017, USA.
VXIplug&play Power Products Instrument Drivers

VXIplug&play instrument drivers for Microsoft Windows 95 and Windows NT are now available on the Web at http://www.agilent.com/find/drivers. These instrument drivers provide a high-level programming interface to your Agilent Technologies electronic load. VXIplug&play instrument drivers are an alternative to programming your instrument with SCPI command strings. Because the instrument driver’s function calls work together on top of the VISA I/O library, a single instrument driver can be used with multiple application environments.

Supported Applications

- Agilent VEE
- Microsoft Visual BASIC
- Microsoft Visual C/C++
- Borland C/C++
- National Instruments LabVIEW
- National Instruments LabWindows/CVI

System Requirements

The VXIplug&play instrument driver complies with the following:

- Microsoft Windows 95
- Microsoft Windows NT 4.0
- HP VISA revision F.01.02
- National Instruments VISA 1.1

Downloading and Installing the Driver

NOTE: Before installing the VXIplug&play instrument driver, make sure that you have one of the supported applications installed and running on your computer.

2. Select the instrument for which you need the driver.
3. Click on the driver, either Windows 95 or Windows NT, and download the executable file to your PC.
4. Locate the file that you downloaded from the Web. From the Start menu select Run \<path>\agxxxx.exe - where <path> is the directory path where the file is located, and agxxxx is the instrument driver that you downloaded.
5. Follow the directions on the screen to install the software. The default installation selections will work in most cases. The readme.txt file contains product updates or corrections that are not documented in the on-line help. If you decide to install this file, use any text editor to open and read it.
6. To use the VXIplug&play instrument driver, follow the directions in the VXIplug&play online help for your specific driver under “Introduction to Programming”.

Accessing Online Help

A comprehensive online programming reference is provided with the driver. It describes how to get started using the instrument driver with Agilent VEE, LabVIEW, and LabWindows. It includes complete descriptions of all function calls as well as example programs in C/C++ and Visual BASIC.

- To access the online help when you have chosen the default Vxipnp start folder, click on the Start button and select Programs | Vxipnp | Agxxxx Help (32-bit).
  - where Agxxxx is the instrument driver.
Introduction To Programming

GPIB Capabilities Of The Power Module

All power module functions except for setting the GPIB address are programmable over the GPIB. The IEEE 488.1 capabilities of the power module are listed in the User’s Guide.

Module GPIB Address

The power module operates from a primary GPIB address that is set by a switch on the mainframe. The power module’s secondary GPIB address is determined by its slot position within the mainframe. See the mainframe Installation Guide for details.

Introduction To SCPI

SCPI (Standard Commands for Programmable Instruments) is a programming language for controlling instrument functions over the GPIB (IEEE 488) instrument bus. SCPI is layered on top of the hardware-portion of IEEE 488.2. The same SCPI commands and parameters control the same functions in different classes of instruments. For example, you would use the same DISPlay command to control the power module display state and the display state of a SCPI-compatible multimeter.

Conventions

The following conventions are used throughout this chapter:

- Angle brackets < > Items within angle brackets are parameter abbreviations. For example, <NR1> indicates a specific form of numerical data.
- Vertical bar | Vertical bars separate one of two or more alternative parameters. For example, 0|OFF indicates that entering either "0" or "OFF" performs the same function.
- Square Brackets [ ] Items within square brackets are optional. The representation [SOURce]:LIST means that SOURce may be omitted.
- Braces { } Braces indicate parameters that may be repeated zero or more times. It is used especially for showing arrays. The notation <A>{<,B>} shows that parameter "A" must be entered, while parameter "B" may be omitted or may be entered one or more times.
- Boldface font Boldface font is used to emphasize syntax in command definitions. TRIGger:DELay <NRf> shows a command definition.
- Computer font Computer font is used to show program lines in text. TRIGger: DELay .5 shows a program line.
Types of SCPI Messages

There are two types of SCPI messages, program and response.

- A **program message** consists of one or more properly formatted SCPI commands sent from the controller to the power module. The message, which may be sent at any time, requests the power module to perform some action.

- A **response message** consists of data in a specific SCPI format sent from the power module to the controller. The power module sends the message only when commanded by a special program message called a "query."

Types of SCPI Commands

SCPI has two types of commands, common and subsystem. **Common** commands generally are not related to specific operation but to controlling overall power module functions, such as reset, status, and synchronization. All common commands consist of a three-letter mnemonic preceded by an asterisk:

```
*RST  *IDN?  *SRE 8
```

**Subsystem** commands perform specific power module functions. They are organized into an inverted tree structure with the "root" at the top (see Figure 3-2). Some are single commands while others are grouped within specific subsystems.

Note If you have the optional Agilent 66001A MPS Keyboard, you may want to use it as a quick introduction to message structure. See "Appendix A".

Structure of a SCPI Message

SCPI messages consist of one or more message units ending in a message terminator. The terminator is not part of the syntax, but implicit in the way your programming language indicates the end of a line (such as a newline or end-of-line character).

The Message Unit

The simplest SCPI command is a single message unit consisting of a command header (or keyword) followed by a message terminator.

```
ABOR
VOLT?
```

The message unit may include a parameter after the header. The parameter usually is numeric, but it can be a string:

```
VOLT 20
VOLT MAX
```

Combining Message Units

The following command message is briefly described here, with details in subsequent paragraphs.
The basic parts of the above message are:

<table>
<thead>
<tr>
<th>Message Component</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Headers</td>
<td>VOLT LEV PROT CURR</td>
</tr>
<tr>
<td>Header Separator</td>
<td>The colon in VOLT:LEV</td>
</tr>
<tr>
<td>Data</td>
<td>8.0 8.8</td>
</tr>
<tr>
<td>Data Separator</td>
<td>The space in VOLT 8.0 and PROT 8.8</td>
</tr>
<tr>
<td>Message Units</td>
<td>VOLT:LEV 8.0 PROT 8.8 CURR?</td>
</tr>
<tr>
<td>Message Unit Separator</td>
<td>The semicolons in VOLT: LEV 8.0; and PROT 8.8;</td>
</tr>
<tr>
<td>Root Specifier</td>
<td>The colon in PROT 8.8; : CURR?</td>
</tr>
<tr>
<td>Query Indicator</td>
<td>The question mark in CURR?</td>
</tr>
<tr>
<td>Message Terminator</td>
<td>The &lt;NL&gt; (newline) indicator. Terminators are not part of the SCPI syntax.</td>
</tr>
</tbody>
</table>

**Parts of a SCPI Message**

**Headers**

*Headers* are instructions recognized by the power module interface. Headers (which are sometimes known as "keywords") may be either in the long form or the short form.

- **Long Form** The header is completely spelled out, such as VOLTAGE, STATUS, and DELAY.
- **Short Form** The header has only the first three or four letters, such as VOLT, STAT, and DEL.

Short form headers are constructed according to the following rules:

- If the header consists of *four or fewer* letters, use all the letters. *(DFI LIST)*
- If the header consists of *five or more* letters and the fourth letter is *not* a vowel (a,e,i,o,u), use the first four letters. *(CURRent STATus)*
- If the header consists of *five or more* letters and the fourth letter is a vowel (a,e,i,o,u), use the first three letters. *(DELay RELay)*

You must follow the above rules when entering headers. Creating an arbitrary form, such as **POLAR** for **POLarity**, will result in an error.
The SCPI interface is not sensitive to case. It will recognize any case mixture, such as TRIGGER, Trigger, TRIgger, triGgeR.

**Note**  
Shortform headers result in faster program execution.

**Header Convention.** In this manual, headers are emphasized with **boldface** type. The proper short form is shown in upper-case letters, such as **DElay**.

**Header Separator.** If a command has more than one header, you must separate them with a colon (**VOLT: PROT OUTPut:RELay:POLarity**).

**Optional Headers.** The use of some headers is optional. Optional headers are shown in brackets, such as **OUTPut[: STATE] ON**. However, if you combine two or more message units into a compound message, you may need to enter the optional header. This is explained under "Traversing the Command Tree."

**Note**  
The optional Agilent 66001A MPS Keyboard does not display optional headers.

**Query Indicator**

Following a header with a question mark turns it into a query (**VOLT?, VOLT:PROT?**). If a query contains a parameter, place the query indicator at the end of the last header (**VOLT: PRO? MAX**).

**Message Unit Separator**

When two or more message units are combined into a compound message, separate the units with a semicolon (**STATus:OPERation?;QUEStionable?**). You can combine message units only at the current path of the command tree (see "Traversing the Command Tree").

**Root Specifier**

When it precedes the first header of a message unit, the colon becomes the root specifier. It indicates that the parser is at the root or top node of the command tree. Note the difference between root specifiers and header separators in the following examples:

```plaintext
OUTP:PROT:DEL .1
:OUTP:PROT:DEL .1
OUTP: PROT: DEL . 1; :VOLT 12.5
```

All colons are header separators.

Only the first colon is a root specifier.

Only the third colon is a root specifier.

**Message Terminator**

A terminator informs SCPI that it has reached the end of a message. Three permitted messages terminators are:

- newline (<NL>), which is ASCII decimal 10 or hex 0A.
- end or identify (<END>)
- both of the above (<NL><END>).

In the examples of this guide, there is an assumed message terminator at the end of each message. If the terminator needs to be shown, it is indicated as <NL> regardless of the actual terminator character.
**Traversing the Command Tree**

Figure 2-2 shows a portion of the subsystem command tree (you can see the complete tree in Figure 3-2). Note the location of the **ROOT** node at the top of the tree. The SCPI interface is at this location when:

- The power module is powered on.
- A device clear (DCL) is sent to the power module.
- The interface encounters a message terminator.
- The interface encounters a root specifier.

![Figure 2-2. Partial Command Tree](image)

**Active Header Path**

In order to properly traverse the command tree, you must understand the concept of the active header path. When the power module is turned on (or under any of the other conditions listed above), the active path is at the root. That means the interface is ready to accept any command at the root level, such as **OUTPUT** or **STATUS** in Figure 2-2. Note that you do not have to proceed either command with a colon; there is an implied colon in front of every root-level command.

If you enter **OUTPUT**, the active header path moves one colon to the right. The interface is now ready to accept **STATE**, **PROTECTION**, or **RELAY** as the next header. Note that you must include the colon, because it is required between headers.

If you now enter **PROTECTION**, the active path again moves one colon to the right. The interface is now ready to accept either **CLEAR** or **DELAY** as the next header.

If you now enter **CLEAR**, you have reached the end of the command string. The active header path remains at **CLEAR**. If you wished, you could have entered **CLEAR; DELAY 20** and it would be accepted. The entire message would be **OUTPUT:PROTECTION:CLEAR;DELAY 20**. The message terminator after **DELAY 20** returns the path to the root.

**The Effect of Optional Headers**

If a command includes optional headers, the interface assumes they are there. For example, if you enter **OUTPUT OFF**, the interface recognizes it as **OUTPUT: STATE OFF** (see Figure 2-2). This returns the active path to the root (**OUTPUT**). But if you enter **OUTPUT: STATE OFF**, then the active path remains at **STATE**. This allows you to send **OUTPUT: STATE OFF; PROTECTION: CLEAR** in one message. If you tried to send **OUTPUT OFF;PROTECTION:CLEAR**, the header path would return to **OUTPUT** instead of **PROTECTION**.
The optional header **SOURCE** precedes the current, list, and voltage subsystems (see Figure 3-2). This effectively makes :CURRENT, :LIST, and :VOLTAGE root-level commands.

**Note**  The optional Agilent 66001 Keyboard does not display optional headers.

### Moving Among Subsystems

In order to combine commands from different subsystems, you need to be able to restore the active path to the root. You do this with the root specifier (:). For example, you could clear the output protection and check the status of the Operation Condition register as follows (see Figure 2-2):

```
OUTPUT:PROTECTION:CLEAR
STATUS:OPERATION:CONDITION?
```

By using the root specifier, you could do the same thing in one message:

```
OUTPUT:PROTECTION:CLEAR::STATUS:OPERATION:CONDITION?
```

**Note**  The SCPI parser traverses the command tree as described in Appendix A of the IEEE 488.2 standard. The "Enhanced Tree Walking Implementation" given in that appendix is not implemented in the power module.

The following message shows how to combine commands from different subsystems as well as within the same subsystem (see Figure 3-2):

```
VOLTAGE:LEVEL 7;PROTECTION 8;:CURRENT:LEVEL 3;MODE LIST
```

Note the use of the optional header **LEVEL** to maintain the correct path within the voltage and current subsystems and the use of the root specifier to move between subsystems.

### Including Common Commands

You can combine common commands with system commands in the same message. Treat the common command as a message unit by separating it with the message unit separator. Common commands *do not affect the active header path*; you may insert them anywhere in the message.

```
VOLT:TRIG 7.5;INIT:*TRG
OUTP OFF:*RCL 2;OUTP ON
```

### SCPI Data Formats

All data programmed to or returned from the power module is ASCII. The data may be *numerical* or *character string*.

### Numerical Data

Table 2-1 and Table 2-2 summarize the numerical formats.
Table 2-1. Numerical Data Formats

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Data Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;NR1&gt;</td>

</table>

Boolean Data

Either form 1 | 0 or ON | OFF may be sent with commands. Queries always return 1 or 0.

OUTPut OFF
CURRent:PROTection 1

String Data

Strings are used for both program (listening) and response (talking) data. String content is limited to the characters required for the link command parameters (see "Chapter 3 - Language Dictionary").

Note

The IEEE 488.2 format for a string parameter requires that the string be enclosed within either single (’ ’) or double (" ") quotes. Be certain that your program statements comply with this requirement.

Character Data

Character strings returned by query statements may take either of the following forms, depending on the length of the returned string:

<CRD>  Character Response Data. Permits the return of character strings.
<AARD> Arbitrary ASCII Response Data. Permits the return of undelimited 7-bit ASCII. This data type has an implied message terminator.
System Considerations

The remainder of this chapter addresses some system issues concerning programming. These are power module addressing and the use of the following types of GPIB system interfaces:

1. HP Vectra PC controller with Agilent 82335A GPIB Interface Command Library
2. IBM PC controller with National Instruments GPIB-PCII Interface/Handler
3. Agilent controller with Agilent BASIC Language System

Note Some specific application programs are given in Appendix B.

Assigning the GPIB Address in Programs

The power module address cannot be set remotely. It is determined by the position of the mainframe address switch and the position of power module (slot position) within the mainframe. (See the Mainframe Users Guide for details.)

The following examples assume that the GPIB select code is 7, the mainframe interface address is 6, and that the power module address will be assigned to the variable PM3 (power module in the third mainframe slot).

1060 ! Power Module installed in Primary Mainframe
1070 PM3=70602 ! Agilent 82335A Interface
1070 ASSIGN @PM3 TO 70602 ! Agilent BASIC Interface
1080 !
1080 ! Power Module installed in Auxiliary Mainframe
1090 PM=70610 ! Agilent 82335A Interface
1090 ASSIGN @PM3 TO 70610 ! Agilent BASIC Interface

For systems using the National Instruments DOS driver, the address is specified in the software configuration program (IBCONFIG.EXE) and assigned a symbolic name. The address then is referenced only by this name within the application program (see the National Instruments GPIB documentation).

DOS Drivers

Types of Drivers

The Agilent 82335A and National Instruments GPIB are two popular DOS drivers. Each is briefly described here. See the software documentation supplied with the driver for more details.

Agilent 82335A Driver. For GW-BASIC programming, the GPIB library is implemented as a series of subroutine calls. To access these subroutines, your application program must include the header file SETUP.BAS, which is part of the DOS driver software.

SETUP.BAS starts at program line 5 and can run up to line 999. Your application programs must begin at line 1000. SETUP.BAS has built-in error checking routines that provide a method to check for GPIB errors during program execution. You can use the error-trapping code in these routines or write your own code using the same variables as used by SETUP.BAS.

National Instruments GPIB Driver. Your program must include the National Instruments header file DECL.BAS. This contains the initialization code for the interface. Prior to running any applications programs, you must set up the interface with the configuration program (IBCONF.EXE).
Your application program will not include the power module symbolic name and GPIB address. These must be specified during configuration (when you run IBCONF.EXE). Note that the primary address range is from 0 to 30 but any secondary address must be specified in the address range of 96 to 126. The power supply expects a message termination on EOI or line feed, so set EOI w/last byte of Write. It is also recommended that you set Disable Auto Serial Polling.

All function calls return the status word IBSTA%, which contains a bit (ERR) that is set if the call results in an error. When ERR is set, an appropriate code is placed in variable IBERR %. Be sure to check IBSTA %, after every function call. If it is not equal to zero, branch to an error handler that reads IBERR% to extract the specific error.

**Error Handling**

If there is no error-handling code in your program, undetected errors can cause unpredictable results. This includes "hanging up" the controller and forcing you to reset the system. Both of the above DOS drivers have routines for detecting program execution errors.

**Important** Use error detection after every call to a subroutine.

**Agilent BASIC Controllers**

The Agilent BASIC Programming Language provides access to GPIB functions at the operating system level. This makes it unnecessary to have the header files required in front of DOS applications programs. Also, you do not have to be concerned about controller "hangups" as long as your program includes a timeout statement. Because the power module can be programmed to generate SRQ on errors, your program can use an SRQ service routine for decoding detected errors. The detectable errors are listed in "Chapter 5 - Error Messages".

**TRANSLATION AMONG LANGUAGES**

This section explains how to translate between Agilent BASIC and several other popular programming environments. For explicit information on initializing interface cards or syntax of language, see the documentation that accompanies your GPIB interface product.

**General Setup Information for GWBASIC**

**Using the Agilent 82335A/82990A/61062B GPIB Command Library**

- When CALLs are made to the GPIB Command Library, all parameters are passed as variables.
- The address of a module is a real number, determined in the same manner as in Agilent BASIC. For example, the address 70501 means 7 is the select code of the GPIB interface, 05 is the GPIB address of the mainframe, 01 is the slot number (secondary address) of the module.
- The module expects each command to be terminated by line feed (character 10) and/or EOI. The default configuration of the GPIB Command Library is carriage return + line feed for end-of-line termination and EOI at the end of a line. Therefore, the defaults are correct for use with the module.
- The GPIB Command Library supports strings, numeric and array data formats. However, multiple data types cannot be sent in a single command. To send both string and numeric data in one command, convert all numeric data to strings, concatenate with the string data and send the combined string to the module. To read multiple data types, read the data into a string, and then manipulate the string by converting each piece into the appropriate data format.
- Error handling is accomplished by checking the variable PCIB.ERR. If it is nonzero, an error has occurred. See the command library documentation for trapping and interpreting this error variable.
Using the National Instruments GPIB Interface

- When CALLs are made to the GPIB driver, all parameters are passed as variables.
- The module is identified as a device in two ways. First, the GPIB.COM driver is modified to include the module. Use the mainframe address as the primary bus address and the slot address as the secondary address. The driver requires secondary address 0 (which is for slot 0) to be entered as 96, secondary address 1 to be entered as 97, etc.
- It is recommended that you disable auto serial poll in the GPIB.COM driver.
- The module expects each command to be terminated by a line feed (character 10) and/or EOI. Configure the GPIB.COM driver to terminate all reads and writes with EOI.
- The GPIB driver does all communication via strings. To send numeric data, number to-string conversion must be performed before the IBWRT( ). To read numeric data, string-to-number conversion must be performed after each IBRD( ).
- Error handling is accomplished by checking the variable IBSTA%. If it is less than zero, an error has occurred. See the GPIB interface documentation for trapping and interpreting this error variable.

General Setup Information for Microsoft C

Using the Agilent 82335A/82990A/61062B GPIB Command Library

- The address of a module is of type long and is determined the same as with Agilent BASIC. For example, the address 70501L means 7 is the select code of the GPIB interface, 05 is the GPIB address of the mainframe, 01 is the slot number (secondary address) of the module.
- The module expects each command to be terminated by a line feed (character 10) and/or EOI. The default configuration of the GPIB Command Library is carriage return+line feed for end-of-line termination and EOI at the end of a line. Therefore, the defaults are correct for use with the module.
- The GPIB Command Library supports strings, numeric and array data formats. However, multiple data types cannot be sent in a single command. To send both string and numeric data in one command, convert all numeric data to strings, concatenate with the string data and send the combined string to the module. To read multiple data types, read the data into a string, and then manipulate the string by converting each piece into the appropriate data format.
- Each command library call returns an int. If the value is zero, no error has occurred. Error handling is accomplished by checking the return value. See the command library documentation for interpretation of this error value.

Using the National Instruments GPIB Interface

- The module is identified as a device in two ways. First, the GPIB.COM driver is modified to include the module. Use the mainframe address as the primary bus address. Use the slot address as the secondary address. The driver requires that secondary address 0 (which is for slot 0) be entered as 96, secondary address 1 be entered as 97, etc.
- It is recommended that you disable the auto serial poll in the GPIB.COM driver.
- The module expects each command to be terminated by either a line feed (character 10) and/or EOI. Configure the GPIB.COM driver to terminate all reads and writes with EOI.
- The GPIB driver does all communication via strings. To send numeric data, number to-string conversion must be performed before the IBWRT( ). To read numeric data, string-to-number conversion must be performed after each IBRD( ).
- Error handling is accomplished by checking the variable IBSTA%. If bit 15 is set, an error has occurred. See the GPIB interface documentation for the interpretation of this error variable.
Sending Commands to and Receiving Data from the Module

Sending the Command “VOLT 5”

*Agilent BASIC*

```
2100 OUTPUT 70501;"VOLT 5"  ! where 70501 means 7 is the select code of the GPIB interface 05 is the
2110 ! GPIB address of the mainframe, 01 is the slot number (secondary address)
2120 ! of the module
```

*GWBASIC (Agilent 82335A/82990A/61062B GPIB Command Library)*

```
2100 MODULE.ADDRESS=70501
2110 COMMAND$ - "VOLT 5"
2120 L - LENGTH(COMMAND$)
2130 CALL IOOUTPUTS(MODULE.ADDRESS,COMMAND$,L)
2140 IF PCIB.ERR&<>O THEN ERROR PCIB.BASERR’   ! ERROR TRAP
```

*National Instruments GPIB Interface*

```
2100 COMMANDS = "VOLT 5"
2110 CALL IBWRT(MODULE.ADDRESS%, COMMAND$)
2120 IF IBSTA% &< 0 GOTO 5000   ! TRAP ERROR WITH ERROR HANDLER
   AT LINE 5000
```

Sending the Command “VOLT 5” in BASIC

*Microsoft C (Agilent 82335A/82990A/61062B HPIB Command Library)*

```
/* Assumes that you have an error handler routine, called ‘error_handler’ that accepts a float. The error handler in then passed the float
that is returned from each call to the library. */

*include &<stdio.h>
*include &<chpib.h>
*include &<cfunc.h>

*define module_address 70501L

char *cmd;
    cmd = "VOLT 5";
    error = iooutputs(MODULE_ADDRESS, cmd, strlen(cmd));
    error_handler(error);
```

*National Instruments GPIB Interface*

```
/* Assumes that you have an error handler routine, called ‘error-handler’. The error handler is then passed the float that is returned from
each call to the library. */

*include &<stdio.h>
*include &<decl.h>

*define ERR (!&<c<15) /* Error is detected as bit i5 of ibsta */

int module-address;   /* Device is configured in the GPIB.COM handler. Use ibfind() to assign a value to module-address. */

char *cmd;
    cmd - "VOLT 5";
    ibwr(MODULE_ADDRESS, cmd, strlen(cmd));
    if (ibsta & ERR)
        error_handler();
```

measured_value = atof(measurement); /* Converts measurement string to float */

Receiving Module Data with C
Language Dictionary

Introduction

This section gives the syntax and parameters for all the IEEE 488.2 SCPI commands and the Common commands used by the Agilent Series 6610xA power modules. It is assumed that you are familiar with the material in "Chapter 2 - Introduction to Programming". That chapter explains the terms, symbols, and syntactical structures used here and gives an introduction to programming.

The programming commands function the same way in all Agilent Series 6610xA power modules. Since SCPI syntax remains the same for all programming languages, the examples are generic.

Syntax definitions use the long form, but only short form headers (or "keywords") appear in the examples. If you have any concern that the meaning of a header in your program listing will not be obvious at some later time, then use the long form to help make your program self-documenting.

Parameters

Most commands require a parameter and all queries will return a parameter. The range for a parameter may vary according to the model of power module. Parameters for all current models are listed in Table 3-3, at the end of this chapter.

Related Commands

Where appropriate, related commands or queries are included. These are listed either because they are directly related by function or because reading about them will clarify or enhance your understanding of the original command or query.

Order of Presentation

The dictionary is organized as follows:

- IEEE 488.2 common commands, in alphabetical order.
- Subsystem commands.

COMMON Commands

Common commands begin with an * and consist of three letters (command) or three letters and a ? (query). Common commands are defined by the IEEE 488.2 standard to perform some common interface functions. The Agilent Series 6610xA power modules respond to the 13 required common commands that control status reporting, synchronization, and internal operations. The power modules also respond to five optional common commands controlling triggers, power-on conditions, and stored operating parameters.

Subsystem Commands

Subsystem commands are specific to power module functions. They can be a single command or a group of commands. The groups are comprised of commands that extend one or more levels below the root. The description of subsystem commands follows the description of the common commands.
Description Of Common Commands

Figure 3-1 shows the common commands and queries. These commands are listed alphabetically in the dictionary. If a command has a corresponding query that simply returns the data or status specified by the command, then both command and query are included under the explanation for the command. If a query does not have a corresponding command or is functionally different from the command, then the query is listed separately. The description for each common command or query specifies any status registers affected. In order to make use of this information, you must refer to "Chapter 4 - Status Reporting", which explains how to read specific register bits and use the information that they return.

*CLS

Meaning and Type
Clear Status  Device Status

Description
This command causes the following actions (see "Chapter 4 - Status Reporting" for descriptions of all registers):

- Clears the following registers:
  - Standard Event Status
  - Operation Status Event
  - Questionable Status Event
  - Status Byte
- Clears the Error Queue
• If *CLS immediately follows a program message terminator (<NL>), then the output queue and the MAV bit are also cleared.

<table>

<td>(None)</td>
</tr>
</tbody>
</table>

**ESE**

**Meaning and Type**

*Event Status Enable*  
Device Status

**Description**

This command programs the Standard Event Status Enable register bits. The programming determines which events of the Standard Event Status Event register (see *ESR?) are allowed to set the ESB (Event Summary Bit) of the Status Byte register. A "1" in the bit position enables the corresponding event. All of the enabled events of the Standard Event Status Event register are logically ORed to cause the Event Summary Bit (ESB) of the Status Byte register to be set. See "Chapter 4 - Status Reporting" for descriptions of all three registers.

**Bit Configuration of Standard Event Status Enable Register**

<table>
<thead>

<td>*ESR? *PSC *STB?</td>
</tr>
</tbody>
</table>

**CAUTION** If PSC is programmed to 0, then the *ESE command causes a write cycle to nonvolatile memory. The nonvolatile memory has a finite maximum number of write cycles (see in the power module User’s Guide). Programs that repeatedly cause write cycles to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.

**ESR?**

**Meaning and Type**

*Event Status Register*  
Device Status

**Description**

This query reads the Standard Event Status Event register. Reading the register clears it. The bit configuration of this register is the same as the Standard Event Status Enable register (*ESE). See "Chapter 4 - Status Reporting" for a detailed explanation of this register.

<table>
<thead>

Example
Agilent Technologies,66101A,0,A.00.01

Related Commands
(Non)

*OPC

Meaning and Type
Operation Complete Device Status

Description
This command causes the interface to set the OPC bit (bit 0) of the Standard Event Status register when the power module has completed all pending operations. (see *ESE for the bit configuration of the Standard Event Status register.) Pending operations are complete when:

- All commands sent before *OPC have been executed. This includes overlapped commands. Most commands are sequential and are completed before the next command is executed. Overlapped commands are executed in parallel with other commands. Commands that affect output voltage, current or state, relays, and trigger actions are overlapped with subsequent commands sent to the power module. The *OPC command provides notification that all overlapped commands have been completed.
- Any change in the output level caused by previous commands has been completed (completion of settling time, relay bounce, etc.)
- All triggered actions are completed.

*OPC does not prevent processing of subsequent commands but Bit 0 will not be set until all pending operations are completed.

<table>
<thead>
<tr>

<th>*OPC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters</td>
<td>(Non)</td>
</tr>
<tr>
<td>Related Commands</td>
<td>*OPC? *WAI</td>
</tr>
</tbody>
</table>

*OPC?

Meaning and Type
Operation Complete Device Status

Description
This query causes the interface to place an ASCII "1" in the Output Queue when all pending operations are completed. Pending operations are as defined for the *OPC command. Unlike *OPC, *OPC? prevents processing of all subsequent commands. *OPC? is intended to be used at the end of a command line so that the application program can then monitor the bus for data until it receives the "1" from the power module Output Queue.
Do not follow *OPC? with *TRG or GPIB bus triggers. Such triggers sent after *OPC? will be prevented from executing and will prevent the power module from accepting further commands. If this occurs, the only programmable way to restore operation is by sending the power module a GPIB DCL (Device Clear) command.

*PSC

Meaning and Type
Power-on Status Clear  Device Initialization

Description
This command controls the automatic clearing at power on the following registers (see "Chapter 4 - Status Reporting" for register details):

- Service Request Enable.
- Standard Event Status Control.

If the command parameter = 1 (or any non-zero value), then the above registers are cleared at power on. If the command parameter = 0, then the above registers are not cleared but are programmed to their last state prior to power turn on. This is the most common application for *PSC and enables the power module to generate an SRQ (Service Request interrupt) at power on.

</table>

---

*PSC causes a write cycle to nonvolatile memory. If *PSC is programmed to 0, then the *ESE and *SRE commands also cause a write cycle to nonvolatile memory. The nonvolatile memory has a finite number of write cycles (see Table 1-2 in the power module User’s Guide). Programs that repeatedly write to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.
**RCL**

*Meaning and Type*

**Recall** Device State

**WARNING** Recalling a previously stored state may place hazardous voltage at the power module output.

**Description**

This command restores the power module to a state that was previously stored in memory with a *SAV command to the specified location. The following states are recalled:

<table>
<thead>
<tr>
<th>CAL:AUTO</th>
<th>LIST:COUN</th>
<th>OUTP:REL:STAT</th>
<th>TRIG:LINK</th>
</tr>
</thead>
<tbody>
<tr>
<td>INIT:CONT</td>
<td>OUTP:PROT:DEL</td>
<td>TRIG:DEL</td>
<td></td>
</tr>
</tbody>
</table>

Sending *RCL also does the following:
- Forces an ABORt command before resetting any parameters (this cancels any uncompleted trigger actions).
- Disables the calibration function by setting CAL:STATe to OFF.

The device state stored in location 0 is automatically recalled at power turn-on when the power module configuration switch is set for this mode of operation (see the power module User’s Guide).

**Note** Whenever the power module is powered up, the state stored in location 0 is written to the 5 volatile locations (5 through 9).

**Command Syntax** *RCL <NRf>*

**Parameters** 0 through 9

**Example** *RCL 3*

**Query Syntax** (None)

**Related Commands** *PSC *RST *SAV

**RST**

*Meaning and Type*

**Reset** Device State

**Description**

This command resets the power module to a factory-defined state as defined below. *RST also forces an ABORt command.

28 Language Dictionary
**SAV**

**Meaning and Type**  
*Save*  Device State

**Description**  
This command stores the present state of the power module to a specified location in memory. Up to 10 states can be stored. Storage locations 0 through 4 are in nonvolatile memory and locations 5 through 9 are in volatile memory. If a particular state is desired at power on, it should be stored in location 0. It then will be recalled at power on if the power module configuration switch is set for this mode of operation (see the power module User’s Guide).

The following power module states are stored by *SAV*:

```
CAL:AUTO  LIST:COUN  OUTP:REL[:STAT]  TRIG:LINK
CURR:MODE  OUTP[:STAT]  OUTP:TTL[:STAT]  VOLT[:LEV][:IMM]
INIT:CONT  OUTP:PROT:DEL  TRIG:DEL
```

**SRE**

**Meaning and Type**  
*Service Request Enable*  Device Interface

**Description**  
This command sets the condition of the Service Request Enable register. This register determines which bits from the Status Byte register (see *STB* for its bit configuration) are allowed to set the Master Status Summary (MSS) bit and the Request for Service (RQS) summary bit. A 1 in any Service Request Enable register bit position enables the corresponding Status Byte register bit and all such enabled bits then are logically ORed to cause Bit 6 of the Status Byte register to be set. See “Chapter 4 - Status Reporting” for more details concerning this process.

When the controller conducts a serial poll in response to SRQ, the RQS bit is cleared, but the MSS bit is not. When *SRE* is cleared (by programming it with 0), the power module cannot generate an SRQ to the controller.

```
Command Syntax  *SRE <NRf>
Parameters  0 to 255
Default Value  (See *PSC*)
Example  *SRE 20
Query Syntax  *SRE?
Returned Parameters  <NR1>  (Register binary value)
Related Commands  *ESE  *ESR  *PSC
```
If *PSC is programmed to 0, then the *SRE command causes a write cycle to nonvolatile memory. The nonvolatile memory has a finite number of write cycles (see Table 1-2 in the power module User’s Guide). Programs that repeatedly write to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.

*STB?

**Meaning and Type**

*Status Byte*   Device Status

**Description**

This query reads the Status Byte register, which contains the status summary bits and the Output Queue MAV bit. Reading the Status Byte register does not clear it. The input summary bits are cleared when the appropriate event registers are read (see “Chapter 4 - Status Reporting”) for more information). The MAV bit is cleared at power on or by *CLS.

A serial poll also returns the value of the Status Byte register, except that bit 6 returns Request for Service (RQS) instead of Master Status Summary (MSS). A serial poll clears RQS, but not MSS. When MSS is set, it indicates that the power module has one or more reasons for requesting service.

**Bit Configuration of Status Byte Register**

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>

</tbody>
</table>

ESB = Event status byte summary; M = Message available
MSS = Master status summary; OPER = Operation status summary;
QUES = Questionable status summary; RQS = Request for service

\(^1\) Also represents RQS. \(^2\) These bits are always zero.

**Query Syntax**

*STB?

**Returned Parameters**

<NR1> (Register binary value)

**Related Commands**

(None)

*TRG

**Meaning and Type**

*Trigger*   Device Trigger

**Description**

This command generates a trigger to any subsystem that has BUS selected as its source (for example, TRIG:SOUR BUS, OUTP:TTL:T:SOUR BUS). The command has the same affect as the Group Execute Trigger (<GET>) command.

**Command Syntax**

*TRG

**Parameters**

(None)

**Query Syntax**

**Description of Subsystem Commands**

Figure 3-2 is a tree diagram of the subsystem commands. Commands followed by a question mark (?) take only the query form. Except as noted in the syntax descriptions, all other commands take both the command and query form. The commands are listed in alphabetical order and the commands within each subsystem are grouped alphabetically under the subsystem.

**ABOR**

This command cancels any trigger actions presently in process. Pending trigger levels are reset equal to their corresponding immediate values. ABOR also cancels any programmed lists that may be in process.

ABOR also resets the WTG bit in the Operation Condition Status register (see "Chapter 4 - Status Reporting"). If INIT:CONT ON has been programmed, the trigger subsystem initiates itself immediately after ABOR, thereby setting WTG. ABOR is executed at power turn on and upon execution of *RCL, RST, or any implied abort command (see List Subsystem).

<table>

Calibration Subsystem

The commands in this subsystem allow you to do the following:
- Control automatic calibration of the measurement subsystem.
- Enable and disable the calibration mode.
- Change the calibration password.
- Calibrate the overvoltage protection (OVP) circuit.
- Calibrate the current and voltage output levels, and store new calibration constants in nonvolatile memory.

**CAL:AUTO**

This command controls the autocalibration function and is used to substantially improve the accuracy of the **MEAS:CURR?** and **MEAS:VOLT?** data readback queries. It does this by compensating for temperature drift in the readback circuitry.
Whenever **CAL:AUTO ONCE** is sent, the power module performs an immediate readback temperature compensation. **CAL:AUTO ONCE** is a sequential command that takes several seconds to complete. When **CAL:AUTO ON** is sent, the power module automatically performs a readback temperature compensation before executing every **MEAS** command. Use of this command extends the execution time of every **MEAS** query.

<table>
<thead>
<tr>

<tr>
<td>Related Commands</td>
<td><strong>MEAS:CURR</strong>?</td>
<td><strong>MEAS:VOLT</strong>?</td>
</tr>
</tbody>
</table>

**CAL:CURR**

This command can only be used in the calibration mode. It enters a current value that you obtain by reading an external meter. You must first select a calibration level (**CAL:CURR:LEV**) for the value being entered. Two successive values (one for each end of the calibration range) must be selected and entered. The power module then computes new current calibration constants. These constants are not stored in nonvolatile memory until saved with the **CAL:SAVE** command.

<table>
<thead>
<tr>
<th>Command Syntax</th>

</tr>
<tr>
<td>Query Syntax</td>
<td>(None)</td>
</tr>
<tr>
<td>Related Commands</td>
<td><strong>CAL:SAVE</strong></td>
</tr>
</tbody>
</table>

**CAL:CURR:LEV**

This command can only be used in the calibration mode. It sets the power module to a calibration point that is then entered with **CAL:CURR[:DATA]**. During calibration, two points must be entered and the low-end point (MIN) must be selected and entered first.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>CALibrate:CURRent:LEVel &lt;CRD&gt;</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Query Syntax</td>
<td>(None)</td>
</tr>
<tr>
<td>Related Commands</td>
<td><strong>CAL:CURR[:DATA]</strong></td>
</tr>
</tbody>
</table>

**CAL:PASS**

This command can only be used in the calibration mode. It allows you to change the calibration password. Unless it is changed subsequently to shipment, the password is the model number of the power module. A new password is automatically stored in nonvolatile memory and does not have to be stored with the **CAL:SAVE** command.

If the password is set to 0, password protection is removed and the ability to enter the calibration mode is unrestricted.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Query Syntax</td>
<td>(None)</td>
</tr>
<tr>
<td>Related Commands</td>
<td><strong>CAL:STAT</strong></td>
</tr>
</tbody>
</table>
CAL:SAVE
This command can only be used in the calibration mode. It saves any new calibration constants (after a current or voltage calibration procedure has been completed) in nonvolatile memory.

Command Syntax: CALibrate:SAVE
Parameters (None)
Examples CAL:SAVE
Query Syntax (None)
Related Commands CAL:CURR CAL:VOLT CAL:STAT

CAL:STAT
This command enables and disables the calibration mode. The calibration mode must be enabled before the power module will accept any other calibration commands except CAL:AUTO.

The first parameter specifies the enabled or disabled state. The second parameter is the password. It is required if the calibration mode is being enabled and the existing password is not 0. If the second parameter is not entered or is incorrect, an error is generated and the calibration mode remains disabled. The query statement returns only the state, not the password.

Whenever the calibration mode is changed from enabled to disabled, any new calibration constants are lost unless they have been stored with CAL:SAVE.

Command Syntax: CALibrate:STATe <bool> [,<NRf>]
Parameters 0 | OFF | 1 | ON [,<NRf>]
*RST Value OFF
Examples CAL:STAT 1,66102 CAL:STAT OFF
Query Syntax CALibrate:STATe?
Returned Parameters 0 | 1
Related Commands CAL:PASS CAL:SAVE

CAL:VOLT
This command can only be used in the calibration mode. It enters a voltage value that is obtained from an external meter. You must first select a calibration level (CAL:VOLT:LEV) for the value being entered. Two successive values (one for each end of the calibration range) must be selected and entered. The power module then computes new voltage calibration constants. These constants are not stored in nonvolatile memory until saved with the CAL:SAVE command.

Command Syntax: CALibrate:VOLTage[:DATA] <NRf>
Parameters See Table 3-2
_default Suffix V
Examples CAL:VOLT 310.0 MV CAL:VOLT 5.000
Query Syntax CAL:VOLT:STATe?
Related Commands CAL:PASS CAL:SAVE

CAL:VOLT:LEV
This command can only be used in the calibration mode. It sets the power module to a calibration point that is then entered with CAL:VOLT[:DATA]. During calibration, two points must be entered and the low-end point (MIN) must be selected and entered first.

Command Syntax: CALibrate:VOLTage:LEVel <CRD>
Parameters MINimum | MAXimum
Examples CAL:VOLT:LEV MIN CAL:VOLT:LEV MAX
Query Syntax (None)
Related Commands CAL:VOLT[:DATA] CAL:STAT
**CAL:VOLT:PROT**

This command can only be used in the calibration mode. It calibrates the power module overvoltage protection (OV) circuit. The power module output must be enabled and operating in the constant voltage (CV) mode. The power module automatically performs the calibration and stores the new OV constant in nonvolatile memory. **CAL:VOLT:PROT** is a sequential command that takes several seconds to complete.

**Command Syntax:** \[\text{CALibrate}:\text{VOLTage}:\text{PROTection}\]

**Parameters:** (None)

**Example:** CAL:VOLT:PROT

**Query Syntax:** (None)

**Related Commands:** CAL:STAT

---

**Current Subsystem**

This subsystem programs the output current of the power module.

**CURR**

This command directly programs the immediate current level of the power module. The immediate level is the current applied at the output terminals. This command is always active, even when the current subsystem is in the list mode (see CURR:MODE).

**Command Syntax** \[\text{SOURce}]:\text{CURRent}[:\text{LEVel}][:\text{IMMediate}][:\text{AMPLitude}] <\text{NRf}+>

**Parameters**

- Default Suffix: \[\text{SOURce}\]
- *RST Value: CURR 500 MA

**Examples**

- CURR 500 MA
- CURR:LEV .5

**Query Syntax** \[\text{SOURce}]:\text{CURRent}[:\text{LEVel}][:\text{IMMediate}][:\text{AMPLitude}]? \[\text{SOURce}]:\text{CURRent}[:\text{LEVel}][:\text{IMMediate}][:\text{AMPLitude}]? MAX \[\text{SOURce}]:\text{CURRent}[:\text{LEVel}][:\text{IMMediate}][:\text{AMPLitude}]? MIN

**Returned Parameters**

- CURR?
- CURR? MAX returns the maximum programmable current level.
- CURR? MIN returns the minimum programmable current levels.

**Related Commands** *SAV *RCL *RST

---

**CURR:MODE**

This command enables or disables list subsystem control over the power module output current. When programmed with **FIX**, this command prevents the output current from being controlled by the sequencing of points specified by **LIST:CURR**. If the **LIST** parameter is used, then the output current may be changed by the subsequent execution of a list. However, the list mode does not prevent the output current from being set by **CURR** and **RCL**.

**Note**

**CURR:MODE:LIST** is an implied **ABORt** command.
CURR:PROT:STAT

This command enables or disables the power module overcurrent (OC) protection function. If the overcurrent protection function is enabled and the power module goes into constant current (CC) mode, then the output is disabled and the Questionable Condition status register OC bit is set (see "Chapter 4 - Status Reporting"). An overcurrent condition can be cleared with the OUTP:PROT:CLE command after the condition is removed.

Command Syntax [SOURce]:CURRent:PROTection:STATe <bool>

Parameters

| 0 | 1 | OFF | ON |

*RST Value OFF

Examples CURR:PROT:STAT 0 CURR:PROT:STAT OFF

Query Syntax [SOURce]:CURRent:PROTection:STATe?

Returned Parameters 0 | 1

Related Commands OUTP:PROT:CLE OUTP:PROT:DEL *RCL *SAV

CURR:TRIG

This command programs the pending triggered current level of the power module. The pending triggered current level is a stored value that is transferred to the output terminals when a trigger occurs. A pending triggered level is unaffected by subsequent CURR commands and remains in effect until the trigger subsystem receives a trigger or an ABORt command is given. If there is no pending triggered level, then the query form returns the IMMEDIATE current level. In order for CURR:TRIG to be executed, the trigger subsystem must be initiated (see INITiate).

Command Syntax [SOURce]:CURRent[:LEVel]:TRIGgered [:AMPLitude] <NR3>

Parameters See Table 3-2

Default Suffix A

*RST Value See Table 3-2

Examples CURR:TRIG 1200 MA CURR:LEV:TRIG 1.2

Query Syntax [SOURce]:CURRent[:LEVel]:TRIGgered [:AMPLitude]? [SOURce]:CURRent[:LEVel]:TRIGgered [:AMPLitude]? MAXimum [SOURce]:CURRent[:LEVel]:TRIGgered [:AMPLitude]? MIN

Returned Parameters <NR3> CURR:TRIG? returns the presently programmed triggered level. If no triggered level is programmed, the CURR level is returned. CURR:TRIG? MAX and CURR:TRIG? MIN return the maximum and minimum programmable triggered current levels.

Related Commands ABOR CURR[:IMM] CURR:MODE INIT *RST

DISPlay Command

This command turns the power module optional front panel voltage and current displays on and off. It does not affect the annunciators.

Command Syntax DISPlay[:WINDow]:STAT <bool>

Parameters

| 0 | 1 | OFF | ON |

*RST Value ON

Examples DISP:STAT 1 DISP:STAT OFF

Query Syntax DISPlay[:WINDow]:STAT?

Returned Parameters 0 | 1

Related Commands *SAV *RCL

INITiate Command

This command enables the trigger subsystem. When a trigger is enabled, an event on the selected trigger source causes the specified triggering action to occur. If a trigger circuit is not enabled, all trigger commands are ignored. If INIT:CONT is OFF, then INIT enables the trigger subsystem only for a single trigger action. The subsystem must be enabled prior to each subsequent trigger action. If INIT:CONT is ON, then the trigger system is continuously enabled and INIT is redundant.
List Subsystem

This subsystem controls the generation of parameter lists that sequence the power module output through values of voltage and current. Two subsystem commands specify lists of output voltages (LIST:VOLT), and currents (LIST:CURR). A count command (LIST:COUN) determines how many times the power module sequences through a list before that list is completed. A dwell command (LIST:DWEL) specifies the time interval that each value (point) of a list is to remain in effect. A step command (LIST:STEP) determines if a trigger causes a list to advance only to its next point or to sequence through all of its points.

Each list can have from 1 to 20 points. Normally, voltage, current, and dwell lists must have the same number of points, or an error is generated when the first list point is triggered. The exception is a list consisting of only one point. Such a list is treated as if it had the same number of points as the other lists, with all the points having the same value as the one specified point.

| Note | All list subsystem commands (as well as CURR:MODE LIST and VOLT:MODE LIST) are implied ABORt commands. |

LIST:COUN

This command sets the number of times that the list is executed before it is completed. The command accepts parameters in the range 1 through 9.9E37, but any number greater than 65534 is interpreted as INFinity. Use INF if you wish to execute a list indefinitely.

| Command Syntax | [SOURce]:LIST:COUNt <NRf+> |
| Parameters     | 1 to 9.9E37 | INFinity |
| *RST Value     | 1           |
| Examples       | LIST:COUN 3 | LIST:COUNT INF |
| Query Syntax   | [SOURce]:LIST:COUNt? |
| Returned Parameters | <NR3> |
| Related Commands | CURR:MODE LIST:CURR LIST:DWEL LIST:STEP LIST:VOLT VOLT:MODE |

LIST:CURR

This command specifies the output current points in a list. The current points are given in the command parameters, which are separated by commas. Up to 20 points may be entered and the output current values specified by the points will be generated in the same order as they were entered.

| Command Syntax | [SOURce]:LIST:CURRent <NRf+> {,<NRf+>} |
| Parameters     | See Table 3-2 |
| Default Suffix | A |
| Examples       | LIST:CURR 2.5,3.0,3.5 LIST:CURR MAX,2.5,MIN |
| Query Syntax   | (None) |
| Related Commands | CURR:MODE LIST:CURR:POIN? LIST:DWEL |

Language Dictionary 37
LIST:CURR:POIN?

This query returns the number of points specified in LIST:CURR. Note that it returns only the total number of points, not the point values.

Query Syntax     [SOURce]:LIST:CURRent:POINts?

Returned Parameters  <NR1>

Example           LIST:CURR:POIN?

Related Commands  CURR:MODE  LIST:CURR  LIST:DWEL

LIST:DWEL

This command sets the dwell points for the output current list and output voltage list. Each dwell point specifies the time, in seconds, that the output of the power module is to remain at the level specified by the corresponding point in the current or voltage list. At the end of the dwell time, the output of the power module depends upon the following conditions:

- If LIST:STEP AUTO has been programmed, the output automatically changes to the next point in the list.
- If LIST:STEP ONCE has been programmed, the output remains at the present level until a trigger sequences the next point in the list.

Command Syntax  [SOURce]:LIST:DWEL1 <NRf+> {,<NRf+>}

Parameters  0.01 to 65 |MINimum | MAXimum

Default Suffix  $s

Examples   LIST:DWEL .5,.5,1.5

Query Syntax  (None)

Related Commands  CURR:MODE  LIST:COUN  LIST:CURR  LIST:STEP  LIST:VOLT  VOLT:MODE

LIST:DWEL:POIN?

This query returns the number of points specified in LIST:DWEL. Note that it returns only the total number of points, not the point values.

Query Syntax  [SOURce]:LIST:DWFL1:POINts?

Returned Parameters  <NR1>

Example           LIST:DWEL:POIN?

Related Commands  LIST:CURR  LIST:DWEL  LIST:VOLT

LIST:STEP

This command specifies how list sequencing occurs in response to triggers. If LIST:STEP AUTO is sent, then a single trigger causes the list (voltage, current, or dwell) to sequence through all its points. The time that a list remains at each point is as specified in the dwell list. As soon as the dwell interval expires, the list moves to the next point.

If LIST:STEP ONCE is sent, then a single trigger advances a list only one point. After the specified dwell interval, the list remains at that point until the next trigger occurs.

In either mode, triggers that occur during a dwell interval are ignored.

Command Syntax  [SOURce]:LIST:STEP <CRD>

Parameters  AUTO | ONCE

*RST Value  AUTO

Examples   LIST:STEP ONCE

Query Syntax  [SOURce]:LIST:STEP?

Returned Parameters  AUTO | ONCE

Related Commands  CURR:MODE  LIST:COUN  LIST:CURR  LIST:DWEL  LIST:VOLT  VOLT:MODE
LIST:VOLT

This command specifies the output voltage points in a list. The voltage points are given in the command parameters, which are separated by commas. Up to 20 points may be entered and the output voltage values specified by the points will be generated in the same order as they were entered.

Command Syntax: [SOURce]:LIST:VOLTage <NRf+> {,<NRf+>}
Parameters: See Table 3-2
Default Suffix: V
Examples: LIST:VOLT 2.0,2.5,3.0    LIST:VOLT MAX,2.5,MIN
Query Syntax: (None)

LIST:VOLT:POIN?

This query returns the number of points specified in LIST:VOLT. Note that it returns only the total number of points, not the point values.

Query Syntax: [SOURce]:LIST:VOLTage:POINts?
Returned Parameters: <NR1>
Example: LIST:VOLT:POIN?
Related Commands: VOLT:MODE    LIST:VOLT    LIST:DWEL

MEASure Query

This query returns the current measured at the power module output terminals or the voltage measured at the sense terminals. The query format allows two optional parameters for specifying the expected value and desired measurement accuracy. The power module accepts the optional parameters but ignores them.

Query Syntax: MEASure:CURRent[:DC]? [<NRf>], [<NRf>]
MEASure:VOLTage[:DC]? [<NRf>], [<NRf>]
Parameters: (None)
Default Suffix: A for MEAS:CURR?  V for MEAS:VOLT?
Examples: MEAS:CURR? MEAS:VOLT?
Returned Parameters: <NR3>
Related Commands: CAL:AUTO

Output Subsystem

This subsystem controls the power module voltage and current outputs and the optional output relay.

OUTP

This command enables or disables the power module output. The state of a disabled output is a condition of zero output voltage and a model-dependent minimum source current.

If the power module is configured to use the relay option, the command opens the relay contacts when the output is disabled and closes them when it is enabled. Transitions between the output ON and OFF states are sequenced so that the relay is switched while the power mesh is disabled. Use of the second (NORelay) parameter prevents the command from having any effect on the relay; it remains in its existing state when OUTPute is executed. The query form returns the output state, excluding that of the relay (see OUTP:REL?).
OUTP:DFI

This command enables or disables the discrete fault indicator (DFI) signal to the power module backplane.

Command Syntax
OUTPut[:STATe] <bool>

Parameters
0 | OFF, [NORelay] | 1 | ON, [NORelay]

*RST Value
0

Examples
OUTP 1    OUTP:STAT ON, NORELAY

Query Syntax
OUTPut[:STATe]?

Returned Parameters
0 | 1

Related Commands
*RCL   *SAV

OUTP:DFI:LINK

This command specifies which events within the power module are linked to DFI source events.

Command Syntax
OUTPut:DFI[:STATe] <CRD>

Parameters
See Table 3-2

*RST Value
SUM3

Examples
OUTP:DFI:LINK “CC”    OUTP:DFI:LINK “OFF”

Query Syntax
OUTPut:DFI[:STATe]?

Returned Parameters
See Table 3-2

Related Commands
OUTP:DFI:LINK    OUTP:DFI:SOUR

OUTP:DFI:SOUR

This command selects the source for DFI events. The only available source is LINK.

Command Syntax
OUTP:DFI:SOUR <CRD>

Parameters
LINK

*RST Value
LINK

Examples
OUTP:DFI:SOUR LINK

Query Syntax
OUTPut:DFI:SOUR?

Returned Parameters
LINK

Related Commands
OUTP:DFI:LINK    OUTP:DFI[:STAT]

OUTP:PROT

There are two output protection commands that do the following:

OUTP:PROT:CLE

Clears any overvoltage (OV), overcurrent (OC), overtemperature (OT), or remote inhibit (RI) protection features. After this command, the output is restored to the state it was in before the protection feature occurred.
**OUTP: PROT: DEL**

Sets the delay time between the programming of an output change that produces a CV, CC, or UNREG condition and the recording of that condition by the Status Operation Condition register. The delay prevents momentary changes in power module status that can occur during reprogramming from being registered as events by the status subsystem. Since the delay applies to CC status, it also delays the OCP (overcurrent protection) feature. The OVP (overvoltage protection) feature is not affected by this delay.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>OUTPut: PROTection: CLEar</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTPut: PROTection: DELay &lt;NRf+&gt;</td>
<td>(None)</td>
</tr>
</tbody>
</table>

| Parameters | OUTP: PROT: CLE, OUTP: PROT: DEL 0 to 32,767 | MIN | MAX |
| Default Suffix | S |

| *RST Value | 100 (milliseconds) |

| Examples | OUTP: PROT: CLE OUTP: PROT: DEL 75E-1 |

| Query Syntax | OUTP: PROTection: CLEar (None) |

| Returned Parameters | <NR3> |

| Related Commands | OUTP: PROT: CLE (None) |
|                  | OUTP: PROT: DEL *RCL *SAV |

**OUTP: REL**

This command is valid only if the power module is configured for the optional relay connector. Programming OFF opens the relay contacts; programming ON closes them. The relay is controlled independently of the output state. If the power module is supplying power to a load, that power will appear at the relay contacts during switching. If the power module is not configured for the relay connector, sending either relay command generates an error.

| Command Syntax | OUTPut: RElay[:STATe] <bool> |
| Parameters | 0 | 1 | OFF | ON |

| *RST Value | 0 |

| Examples | OUTP: REL 1 OUTP: REL OFF |

| Query Syntax | OUTPut: RElay? |

| Returned Parameters | 0 | 1 |

| Related Commands | OUTP[:STAT] *RCL *SAV |

**OUTP: REL: POL**

This command is valid only if the power module is configured for the optional relay connector. Programming NORMal causes the relay output polarity to be the same as the power module output. Programming REVerse causes the relay output polarity to be opposite to that of the power module output. If OUTP[:STAT] = ON when either relay command is sent, the power module output voltage is set to 0 during the time that the relays are changing polarity. If the power module is not configured for the relay connector, sending either relay command generates an error.

| Command Syntax | OUTPut: RElay: POlarity <CRD> |
| Parameters | NORMal | REVerse |

| *RST Value | NORM |

| Examples | OUTP: REL: POL NORM |

| Query Syntax | OUTPut: RElay: POlarity? |

| Returned Parameters | NORM | REV |

| Related Commands | OUTP[:STAT] *RCL *SAV |
OUTP:TTLT

This command enables or disables the power module Trigger Out signal, which is available at a BNC connector on the rear of the mainframe. Trigger Out is the logical OR of all the power module TTLTrig signals (see "Chapter 5 - Synchronizing Power Module Output Changes"). It also may be selected as a trigger input (see TRIGger:SOURce).

Command Syntax

```
OUTP:TTLT[:STATe] <bool>
```

Parameters

```
0 | 1 | OFF | ON
```

*RST Value

```
OFF
```

Examples

```
OUTP:TTLT 1
```

Query Syntax

```
OUTP:TTLT[:STATe]?
```

Returned Parameters

```
0 | 1
```

Related Commands

```
OUTP:TTLT:LINK OUTP:TTLT:SOUR
```

OUTP:TTLT:LINK

This command specifies which events within the power module are linked to TTLTrg source events when LINK is the parameter for the OUTP:TTLT:SOUR command.

Command Syntax

```
OUTP:TTLT:LINK <CRD>
```

Parameters

```
See Table 3-1
```

*RST Value

```
OFF
```

Examples

```
OUTP:TTLT:LINK "CC" OUTP:TTLT:LINK "OFF"
```

Query Syntax

```
OUTP:TTLT:LINK?
```

Returned Parameters

```
See Table 3-1
```

Related Commands

```
OUTP:TTLT:SOUR OUTP:TTLT[:STAT]
```

OUTP:TTLT:SOUR

This command selects the signal source for the Trig Out signal as follows:

```
BUS *TRG or <GET> (Group Execute Trigger) HOLD No trigger source except TRIG:IMM
EXT Mainframe backplane Trigger In bus LINK Internal power module event as specified by TRIG:LINK
```

When an event becomes true at the selected TTLTrg source, a pulse is sent to the BNC connector on the rear of the mainframe.

Command Syntax

```
OUTP:TTLT:SOURce <CRD>
```

Parameters

```
BUS | EXTERNAL | LINK | HOLD
```

*RST Value

```
BUS
```

Examples

```
OUTP:TTLT:SOUR LINK
```

Query Syntax

```
OUTP:TTLT:SOURce?
```

Returned Parameters

```
BUS | EX | LINK | HOLD
```

Related Commands

```
OUTP:TTLT:LINK OUTP:TTLT[:STAT]
```

Status Subsystem

This subsystem programs the power module status registers. The power module has three groups of status registers: **Operation**, **Questionable**, and **Standard Event**. The Standard Event group is programmed with Common commands as described in "Chapter 4 - Status Reporting". The Operation and Questionable status groups each consist of the following five registers:

Condition Enable Event NTR Filter PTR Filter
**Status Operation Registers**

The bit configuration of all Status Operation registers is shown in the following table:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit Name</td>
<td>STC</td>
<td>NU</td>
<td>CC</td>
<td>NU</td>
<td>CV</td>
<td>NU</td>
<td>NU</td>
<td>WTG</td>
<td>NU</td>
<td>NU</td>
<td>NU</td>
<td>NU</td>
<td>CAL</td>
</tr>
<tr>
<td>Bit Weight</td>
<td>4096</td>
<td>2048</td>
<td>1024</td>
<td>512</td>
<td>256</td>
<td>128</td>
<td>64</td>
<td>32</td>
<td>16</td>
<td>8</td>
<td>4</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

Cal = Interface is computing new calibration constants; CC = The power module is in constant current mode; CV = The power module is in constant voltage mode; NU = (Not used); STC = The list step is complete; WTG = Interface is waiting for a trigger.

**Note**  
See "Chapter 4 - Status Reporting" for more explanation of these registers.

**STAT:OPER?**

This query returns the value of the Operation Event register. The Event register is a read-only register which holds (latches) all events that are passed by the Operation NTR and/or PTR filter. Reading the Operation Event register clears it.

- **Query Syntax:** `STATus:OPERation[:EVEN]t`?
- **Parameters:** (None)
- **Returned Parameters:** `<NR1>` (Register value)
- **Examples:** `STAT:OPER:EVEN?`
- **Related Commands:** `*CLS` `STAT:OPER:NTR` `STAT:OPER:PTR`

**STAT:OPER:COND?**

This command returns the value of the Operation Condition register. That is a read-only register which holds the real-time (unlatched) operational status of the power module.

- **Query Syntax:** `STATus:OPERation:CONDition?`
- **Parameters:** (None)
- **Examples:** `STAT:OPER:COND?`
- **Returned Parameters:** `<NR1>` (Register value)
- **Related Commands:** (None)

**STAT:OPER:ENAB**

This command and its query set and read the value of the Operation Enable register. This register is a mask for enabling specific bits from the Operation Event register to set the operation summary bit (OPER) of the Status Byte register. This bit (bit 7) is the logical OR of all the Operation Event register bits that are enabled by the Status Operation Enable register.

- **Command Syntax:** `STATus:OPERation:ENABle <NR1>`
- **Parameters:** 0 to 32727
- **Suffix:** (None)
- **Default Value:** 0
- **Examples:** `STAT:OPER:ENAB 1312` `STAT:OPER:ENAB 1`
- **Query Syntax:** `STATus:OPERation:ENABle?`
- **Returned Parameters:** `<NR1>` (Register value)
- **Related Commands:** `STAT:OPER:EVEN`
STAT:OPER:NTR|PTR Commands

These commands set or read the value of the Operation NTR (Negative-Transition) and PTR (Positive-Transition) registers. These registers serve as polarity filters between the Operation Enable and Operation Event registers to cause the following actions:

- When a bit in the Operation NTR register is set to 1, then a 1-to-0 transition of the corresponding bit in the Operation Condition register causes that bit in the Operation Event register to be set.
- When a bit of the Operation PTR register is set to 1, then a 0-to-1 transition of the corresponding bit in the Operation Condition register causes that bit in the Operation Event register to be set.
- If the same bits in both NTR and PTR registers are set to 1, then any transition of that bit at the Operation Condition register sets the corresponding bit in the Operation Event register.
- If the same bits in both NTR and PTR registers are set to 0, then no transition of that bit at the Operation Condition register can set the corresponding bit in the Operation Event register.

Note

Setting a bit in the value of the PTR or NTR filter can of itself generate positive or negative events in the corresponding Operation Event register.

Command Syntax

<table>
<thead>
<tr>
<th>STATus:OPERation:NTRansition</th>
<th>STATus:OPERation:PTRansition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters</td>
<td>0 to 32727</td>

<td>0</td>
</tr>
</tbody>
</table>

Examples

STAT: OPER: NTR 32   STAT: OPER: PTR 1312

Query Syntax

STAT:OPER:NTR?    STAT:OPER:PTR?

Returned Parameters

<NRI> (Register value)

Related Commands

STAT:OPER:ENAB

STAT: PRES

This command sets all defined bits in the Status Subsystem PTR registers and clears all bits in the subsystem NTR and Enable registers. STAT:OPER:PTR is set to 1313 and STAT:QUES:PTR is set to 1555.

Command Syntax

STATus:PRESet

Parameters

(None)

Examples

STAT:PRES

Query Syntax

(None)

Related Commands

(None)

Status Questionable Registers

The bit configuration of all Status Questionable registers is as follows:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>15-11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Condition</td>
<td>NU</td>
<td>UNR</td>
<td>RI</td>
<td>NU</td>
<td>NU</td>
<td>NU</td>
<td>NU</td>
<td>OT</td>
<td>NU</td>
<td>NU</td>
<td>OC</td>
<td>OV</td>
</tr>
<tr>
<td>Bit Weight</td>
<td>1024</td>
<td>512</td>
<td>256</td>
<td>128</td>
<td>64</td>
<td>32</td>
<td>16</td>
<td>8</td>
<td>4</td>
<td>2</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

NU = (Not used); OC = Overcurrent protection circuit has tripped; OT = Overtemperature status condition exists; OV = Overvoltage protection circuit has tripped; RI = Remote inhibit is active; UNR = Power supply output is unregulated.

Note

See "Chapter 4 - Status Reporting" for more explanation of these registers.
STAT:QUES?

This command returns the value of the Questionable Event register. The Event register is a read-only register which holds (latches) all events that are passed by the Questionable NTR and/or PTR filter. Reading the Questionable Event register clears it.

<table>
<thead>
<tr>
<th>Query Syntax</th>
<th>Status:QUESTionable[:EVENT]?</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Related Commands</td>
<td>*CLS STAT:QUES:NTR STAT:QUES:PTR</td>
</tr>
</tbody>
</table>

STAT:QUES:COND?

This query returns the value of the Questionable Condition register. That is a read-only register which holds the real-time (unlatched) questionable status of the power module.

<table>
<thead>
<tr>
<th>Query Syntax</th>
<th>Status:QUESTionable:CONDition?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>STAT:QUES:COND?</td>
</tr>
<tr>
<td>Returned Parameters</td>
<td>&lt;NR1&gt; (Register value)</td>
</tr>
<tr>
<td>Related Commands</td>
<td>(None)</td>
</tr>
</tbody>
</table>

STAT:QUES:ENAB

This command sets or reads the value of the Questionable Enable register. This register is a mask for enabling specific bits from the Questionable Event register to set the questionable summary (QUES) bit of the Status Byte register. This bit (bit 3) is the logical OR of all the Questionable Event register bits that are enabled by the Questionable Status Enable register.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Status:QUESTionable:ENABLE &lt;NRf&gt;</th>
</tr>

<td>Status:QUESTionable:ENABLE?</td>
</tr>
<tr>
<td>Returned Parameters</td>
<td>&lt;NR1&gt; (Register value)</td>
</tr>
<tr>
<td>Related Commands</td>
<td>STAT:QUES:EVEN?</td>
</tr>
</tbody>
</table>

STAT:QUES:NTR|PTR Commands

These commands allow the values of the Questionable NTR (Negative-Transition) and PTR (Positive-Transition) registers to be set or read. These registers serve as polarity filters between the Questionable Enable and Questionable Event registers to cause the following actions:

- When a bit of the Questionable NTR register is set to 1, then a 1-to-0 transition of the corresponding bit of the Questionable Condition register causes that bit in the Questionable Event register to be set.
- When a bit of the Questionable PTR register is set to 1, then a 0-to-1 transition of the corresponding bit in the Questionable Condition register causes that bit in the Questionable Event register to be set.
- If the same bits in both NTR and PTR registers are set to 1, then any transition of that bit at the Questionable Condition register sets the corresponding bit in the Questionable Event register.
- If the same bits in both NTR and PTR registers are set to 0, then no transition of that bit at the Questionable Condition register can set the corresponding bit in the Questionable Event register.

Note Setting a bit in the PTR or NTR filter can of itself generate positive or negative events in the corresponding Questionable Event register.
<table>

</tr>
</tbody>
</table>

**SYST:ERR?**

This query returns the next error number followed by its corresponding error message string from the remote programming error queue. The queue is a FIFO (first-in, first-out) buffer that stores errors as they occur. As it is read, each error is removed from the queue. When all errors have been read, the query returns **NO ERROR**. If more errors are accumulated than the queue can hold, the last error in the queue is **TOO MANY ERRORS**.

<table>
<thead>
<tr>
<th>Query Syntax</th>
<th>SYSTem:ERRor?</th>

<td>Example</td>
<td>SYST:VERS?</td>
</tr>
</tbody>
</table>

**Trigger Subsystem**

This subsystem controls the triggering of the power module. See "Chapter 5 - Synchronizing Power Module Output Changes" for an explanation of the Trigger Subsystem.

**Note**

The trigger subsystem must be enabled from the Initiate Subsystem or no triggering action will occur.

**TRIG**

When the trigger subsystem is enabled, **TRIG** generates an immediate trigger signal that bypasses any selected **TRIG:SOUR** and **TRIG:DEL**. The trigger will then:

1. Initiate a pending level change as specified by CURR[:LEV]:TRIG or VOLT[:LEV]:TRIG.
2. Initiate a pending level change as specified by CURR:MODE LIST or VOLT:MODE LIST and in accordance with LIST:STEP.
3. Clear the WTG bit in the Status Operation Condition register.
**TRIG:DEL**

This command sets the time delay between the detection of an event on the specified trigger source and the start of any corresponding trigger action on the power module’s output.

**Command Syntax**

```
TRIgger[:STARt]:DELay <NRf+>
```

**Parameters**

- 0 to 65 | MIN | MAX
- Default Suffix $  
- *RST Value 0
- Examples TRIG:DEL .25 TRIG:DEL MAX
- Query Syntax TRIGger[:STARt]:DELay?
- Returned Parameters <NR3>
- Related Commands ABOR CURR:MODE CURR:TRIG INIT *TRG VOLT:MODE VOLT:TRIG

**TRIG:LINK**

This command specifies which event conditions within the power module are linked to trigger source events when LINK is the parameter of the TRIG:SOUR command.

**Command Syntax**

```
TRIgger[:STARt]:LINK <CRD>
```

**Parameters**

- (See Table 3-1)
- *RST Value OFF
- Examples TRIG:LINK "CC" TRIG:LINK "OPER"
- Query Syntax TRIGger[:STARt]:LINK?
- Returned Parameters <CRD> (See Table 3-1)
- Related Commands ABOR INIT *TRG TRIG[:IMM] TRIG:SOUR

**TRIG:SOUR**

This command selects the power module input trigger source as follows:

- **BUS**  *TRG or <GET> (Group Execute Trigger)
- **EXT** Mainframe backplane Trigger In bus
- **HOLD** No trigger source except TRIG:IMM
- **LINK** Internal power module event as specified by TRIG:LINK
- **TTLT** Mainframe Trigger Out bus

**Command Syntax**

```
TRIgger[:STARt]:SOURce <CRD>
```

**Parameters**

- BUS | EXT | HOLD | LINK | TTLT
- *RST Value BUS
- Examples TRIG: SOUR BUS TRIG: SOUR LINK
- Query Syntax TRIGger[:STARt]:SOURce?
- Returned Parameters BUS | EXT | HOLD | TTLT
- Related Commands ABOR CURR:TRIG INIT OUTP:TTLT VOLT:TRIG
**Voltage Subsystem**

This subsystem programs the output voltage of the power module.

**VOLT**

This command directly programs the immediate voltage level of the power module. The immediate level is the voltage applied at the output terminals. This command is always active, even when the voltage subsystem is in the list mode (see **VOLT:MODE**).

### Command Syntax

```
[SOURce]:VOLTage[:LEVEL][:IMMediate][:AMPLitude] <NRf+>
```

### Parameters
- Default Suffix: Table 3-2
- *RST Value: V

### Examples
- `VOLT 2500 MV`
- `VOLT:LEV 2.5`

### Query Syntax

```
[SOURce]:VOLTage:LEVEL[:IMMediate][:AMPLitude]?  
[SOURce]:VOLTage:LEVEL[:IMMediate][:AMPLitude]?  MAX  
[SOURce]:VOLTage:LEVEL[:IMMediate][:AMPLitude]?  MIN
```

### Returned Parameters
- `<NR3> VOLT?` returns the presently programmed immediate voltage level.
- `VOLT? MAX` and `VOLT? MIN` return the maximum and minimum programmable immediate voltage levels.

### Related Commands
- *SAV
- *RCL
- *RST

**VOLT:MODE**

This command enables or disables list subsystem control over the power module output voltage. When programmed with **FIX**, this command prevents the output voltage from being controlled by the sequencing of points specified by **LIST:VOLT**. If the **LIST** parameter is used, then the output voltage may be changed by the subsequent execution of a list. However, the list mode does not prevent the output voltage from being set by **VOLT[:IMM]** and *RCL.

**Note**

**VOLT:MODE LIST** is an implied **ABORT** command.

### Command Syntax

```
[SOURce]:VOLTage:MODE <CRD>
```

### Parameters
- Default Suffix: Table 3-2
- *RST Value: FIX

### Examples
- `VOLT:MODE LIST`
- `VOLT:MODE FIX`

**VOLT:PROT**

This command sets the overvoltage protection (OVP) level of the power module. If the output voltage exceeds the OVP level, then the power module output is disabled and the Questionable Condition status register OV bit is set (see "Chapter 4 - Status Reporting"). An overvoltage condition can be cleared with the **OUTP:PROT:CLE** command after the condition that caused the OVP trip is removed. The OVP always trips with zero delay and is unaffected by the **OUTP:PROT:DEL** command.

### Command Syntax

```
[SOURce]:VOLTage:PROTection[:LEVEL] <NRf+>
```

### Parameters
- Default Suffix: Table 3-2
- *RST Value: MAX

### Examples
- `VOLT:PROT 2.5`
- `VOLT:PROT:LEV MAX`
VOLT:SENS:SOUR?

This command reads the state of the power module output connector remote sense switch. The INTernal parameter corresponds to the LOCAL position of the switch. (See the power module User’s Guide for more information about this switch.) VOLT:SENS:SOUR is an alias for the SCPI VOLT:ALC:SOUR command.

Query Syntax  SOURce]:VOLTage:SENSe:SOURce?

Example  SOURce]:VOLTage:SENSe:SOURce?

Returned Parameters  EXTERNAL | INTernal

Related Commands  VOLT:ALC:SOUR?

VOLT:TRIG

This command programs the pending triggered voltage level of the power module. The pending triggered voltage level is a stored value that is transferred to the output terminals when a trigger occurs. A pending triggered level is unaffected by subsequent VOLT:LEV[:IMM] commands and remains in effect until the trigger subsystem receives a trigger or an ABORt command is given. In order for VOLT:TRIG to be executed, the trigger subsystem must be initiated (see INITiate).

Command Syntax  SOURce]:VOLTage[:LEVEL]:TRIGgered [:AMPLitude] <NRf+>

Parameters  See Table 3-2

Default Suffix  V

*RST Value  See Table 3-2

Examples  VOLT:TRIG 1200 MV  VOLT:LEV:TRIG 1.2

Query Syntax  SOURce]:VOLTage[:LEVEL]:TRIGgered [:AMPLitude]?

[ SOURce]:VOLTage[:LEVEL]:TRIGgered [:AMPLitude]?

[ SOURce]:VOLTage[:LEVEL]:TRIGgered [:AMPLitude]? MAX

[ SOURce]:VOLTage[:LEVEL]:TRIGgered [:AMPLitude]? MIN

Returned Parameters  <NR3> VOLT:TRIG? returns presently programmed current level. If the TRIG level is not programmed, the IMM level is returned. VOLT:TRIG? MAX and VOLT:TRIG? MIN return the maximum and minimum programmable triggered voltage levels.

Related Commands  ABOR VOLT[:IMM]  VOLT:MODE  INIT  *RST

Status Reporting

Power Module Status Structure

Figure 4-1 shows the status register structure of the power module. The Standard Event, Status Byte, and Service Request Enable registers and the Output Queue perform standard GPIB functions as defined in the *IEEE 488.2 Standard Digital Interface for Programmable Instrumentation*. The Operation Status and Questionable Status registers implement status functions specific to the power module.

Status Register Bit Configuration

Table 4-2 and Figure 4-1 show the bit configuration of each status register.

Operation Status Group

Register Functions

The Operation Status registers record signals that occur during normal operation. The group consists of the following registers:

- A Condition register that holds real-time status of the circuits being monitored. It is a read-only register.
- A PTR/NTR (positive transition/negative transition) Filter that functions as described under \texttt{STAT:OPER:NTR|PTR COMMANDS} in "Chapter 3 - Language Dictionary". This is a read/write register.
- An Event register that latches any condition that is passed through the PTR or NTR filters. Reading the Event register clears it.
- An Enable register that functions as described under \texttt{STAT:OPER:ENAB} in "Chapter 3 - Language Dictionary". This is a read/write register.

The outputs of the Operation Status group are logically-ORed into the OPER(ation) summary bit (7) of the Status Byte register.

Register Commands

Commands that access this group are derived from the \texttt{STAT:OPER} commands described in "Chapter 3 - Language Dictionary" and summarized in Table 4-1.

Questionable Status Group

Register Functions

The Questionable Status registers record signals that indicate abnormal operation of the power module. As shown in Figure 4-1, the group consists of the same type of registers as the Status Operation group. The outputs of the Questionable Status group are logically-ORed into the QUES(tionable) summary bit (3) of the Status Byte register.

Register Commands

Programming for this group is derived from the STAT:QUES commands described in "Chapter 3 - Language Dictionary" and summarized in Table 4-3.

Standard Event Status Group

Register Functions

This group consists of an Event register and an Enable register that are programmed by COMMON commands. The Standard Event register latches events relating to interface communication status (see Table 4-2). It is a read-only register that is cleared when read. The Standard Event Enable register functions similarly to the enable registers of the Operation and Questionable status groups.

Register Commands

The common *ESE command programs specific bits in the Standard Event Status Enable register. Because the power module implements *PSC, the register is cleared at power on if *PSC = 1.

*ESR? reads the Standard Event Status Event register. Reading the register clears it.
Status Byte Register

This register summarizes the information from all other status groups as defined in the IEEE 488.2 Standard Digital Interface for Programmable Instrumentation standard. The bit configuration is shown in Table 4-2. The register can be read either by a serial poll or by *STB?. Both methods return the same data, except for bit 6. Sending *STB? returns MSS in bit 6, while polling returns RQS in bit 6.

The RQS Bit

Whenever the power module requests service, it sets the SRQ interrupt line true and latches RQS into bit 6 of the Status Byte register. When the controller services the interrupt, RQS is cleared inside the register and returned in bit position 6 of the response. The remaining bits of the Status Byte register are not disturbed.

The MSS Bit

This is a real-time (unlatched) summary of all Status Byte register bits that are enabled by the Service Request Enable register. MSS is set whenever the power module has at least one reason (and possible more) for requesting service. Sending *STB? reads the MSS in bit position 6 of the response. No bits of the Status Byte register are cleared by reading it.

Determining the Cause of a Service Interrupt

You can determine the reason for an SRQ by the following actions:

- Use a serial poll or the *STB? query to determine which summary bits are active.
- Read the corresponding Event register for each summary bit to determine which events caused the summary bit to be set. When an Event register is read, it is cleared. This also clears the corresponding summary bit.
- The interrupt will recur until the specific condition that caused the each event is removed. If this is not possible, the event may be disabled by programming the corresponding bit of the status group Enable register or NTRP|PTR filter. A faster way to prevent the interrupt is to disable the service request by programming the appropriate bit of the Service Request Enable register.

Output Queue

The Output Queue is a first-in, first-out (FIFO) data register that stores power module-to-controller messages until the controller reads them. Whenever the queue holds one or more bytes, it sets the MAV bit (4) of the Status Byte register. If too many unread error messages are accumulated in the queue, a system error message is generated (see "Chapter 6 - Error Messages"). The Output Queue is cleared at power on and by *CLS.

Location Of Event Handles

"Event handles" are signals within the interface that can be used for triggers, for a Trigger Out signal, or for a DFI signal. Those event handles derived from signals in the Status Subsystem are shown as circled numbers in Figure 4-1. Other event handles are described in "Chapter 5 - Synchronizing Power Module Output Changes".
Initial Conditions At Power On

Status Registers

When the power module is turned on, a sequence of commands initializes the status registers. Table 4-4 shows the register states and corresponding power-on commands for the factory-default *RST power-on state. If the module power-on function switch is set to 0, then the power-on state is determined by the parameters stored in location 0 (see Chapter 4 of the User’s Guide).

</tr>
</tbody>
</table>

\(^1\)If PSC=1. If PSC = 0, then the last previous state before turn on is recalled. The value of PSC is stored in nonvolatile memory.

The PON (Power On) Bit

The PON bit in the Standard Event register is set whenever the power module is turned on. The most common use for PON is to generate an SRQ at power on following an unexpected loss of power. To do this, bit 7 of the Standard Event Enable register must be set so that a power-on event registers in the ESB (Standard Event Summary Bit). Also, bit 5 of the Service Request Enable register must be set to permit an SRQ to be generated. The commands to accomplish these two conditions are:

*ESE 128
*SRE 32

If *PSC is programmed to 0, the contents of the Standard Event Enable and Service Request Enable registers are saved in nonvolatile memory and recalled at power on. This allows a PON event to generate SRQ at power on. Programming *PSC to 1 prevents these registers from being saved and they are cleared at power on. This prevents a PON event from generating SRQ at power on.

Examples

Note

These examples are generic SCPI commands. See "Chapter 2 - Programming Introduction" for information about encoding the commands as language strings.

Servicing an Operation Status Mode Event

This example assumes you want a service request generated whenever the power module switches to the CC (constant current) mode. From Figure 4-1, note that the required path is for a condition at bit 10 (CC) of the Operation Status register to set bit 6 (RQS) of the Status Byte register. The required register programming is as follows:
Table 4-5. Generating RQS from the CC Event

<table>
<thead>
<tr>
<th>Register</th>
<th>Command</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation PTR</td>
<td>STAT:OPER:PTR 1024</td>
<td>Allows a positive transition at the CC input (bit 10) to be latched into the Status Event register.¹</td>
</tr>
<tr>
<td>Operation Enable</td>
<td>STAT:OPER:ENAB 1024</td>
<td>Allows the latched CC event to be summed into the OPER summary bit.</td>
</tr>
<tr>
<td>Service Request Enable</td>
<td>*SRE 128</td>
<td>Enables the OPER summary bit from the Status Byte register to generate RQS.</td>
</tr>
<tr>
<td>Operation Condition</td>
<td>STAT:OPER:EVEN?</td>
<td>When you service the request, read the event register to determine that bit 10 (CC) is set and to clear the register for the next event.</td>
</tr>
</tbody>
</table>

¹ All bits of the PTR registers bits are set to 1 at power on.

Adding More Operation Events

To add CV (constant voltage) and DWE (dwelling) events to this example, it is only necessary to add the decimal values for bit 8 (value 64) and bit 12 (value 4096) to the programming commands of the Operation Status group. The commands to do this are:

STAT:OPER:PTR 5376;ENAB 5376

It is not necessary to change any other registers, since the programming for the operation summary bit (OPER) path has already been done.

Servicing Questionable Status Events

To add OC (overcurrent) and OT (overtemperature) events to this example, program Questionable Status group bits 1 and 4.

STAT:QUES:PTR 18;ENAB 18

Next, you must program the Service Request Enable register to recognize both the questionable (QUES) and the operational (OPER) summary bits.

*SRE 136

Now when there is a service request, read back both the operational and the questionable event registers.

STAT:OPER:EVEN?;QUES:EVEN?

Monitoring Both Phases of a Status Transition

You can monitor a status signal for both its positive and negative transitions. For example, to generate RQS when the power module either enters the CC (constant current) condition or leaves that condition, program the Operational Status PTR/NTR filter as follows:

STAT:OPER:PTR 1024;NTR 1024
STAT:OPER:ENAB 1024;*SRE 128

The PTR filter will cause the OPER summary bit to set RQS when CC occurs. Then the controller subsequently reads the event register (STAT: OPER: EVEN?), the register is cleared. When CC subsequently goes false, the NTR filter causes the OPER summary bit to again set RQS.
Synchronizing Power Module Output Changes

Introduction

If you use only the VOLT [: LEV] : TRIG and/or CURR [: LEV] : TRIG commands to trigger output changes, you do not need the information in this chapter. This chapter gives supplemental information on how you can synchronize power module output changes to internal or external events. The output changes can be:

- A change in output voltage level.
- A change in output current level.
- The start of an internally-paced list of output voltage or current levels.
- A step to the next level in a list of output voltage or current levels.
- A change in the output state (on or off).

The event to which the output change is synchronized can be any of the following:

- A command from the controller.
- A GPIB bus command.
- An event that occurs within the power module.
- An event that occurs within another power module.
- An external signal at the mainframe trigger input.
- An external signal at the mainframe fault inhibit input (INH).

The output synchronization is implemented by the following power module functions:

- Trigger subsystem.
- List subsystem.
- Remote inhibit (RI) subsystem.
- Discrete fault indicator (DFI) subsystem.

Trigger Subsystem

Two simplified models of the trigger subsystem are presented. The first model shows how the trigger subsystem functions during fixed-mode output. This mode occurs when VOLT:MODE FIX or CURR:MODE FIX is in effect (see "Chapter 3 - Language Dictionary"). In this mode of output control, each triggered output voltage or current value is explicitly specified by a triggered-level command (for example, VOLT: TRIG 20 or CURR: TRIG 1.55). The trigger then causes the output to change to this pending triggered level.

The second model shows the difference in trigger subsystem operation during list-mode output. This mode occurs when the VOLT:MODE LIST or CURR:MODE LIST command is programmed (see "List Subsystem" further in this chapter for an explanation of lists). In this mode of output operation, the triggered output voltage or current levels are specified within a list and the trigger controls the sequencing through the values in the list.

Model of Fixed-Mode Trigger Operation

Figure 5-1A is a simplified model of trigger subsystem operation when the power module is programmed for fixed-mode output. The rectangular boxes represent states. The arrows show the transitions between states. These are labeled with the input or event that causes the transition to occur.
Idle State
When the power module is turned on, the trigger subsystem is in the idle state. In this state, the trigger subsystem ignores all triggers. When the trigger action has been completed, the trigger subsystem returns to this state. It also returns to the Idle state if the ABORT command or an implied ABORT command (*RST, *RCL, or any LIST) is sent.

Initiated State
The INITiate command moves the trigger subsystem from the Idle state to the Initiated State. This enables the power module to receive triggers. The source of the trigger is selected with the TRIGGER:SOURce command (see "Chapter 3 - Language Dictionary"). When in the Initiated state, the power module responds to events on the selected trigger source by transferring to the Delaying state. As shown in Figure 5-1A there is another trigger signal that is not subject to TRIG:SOUR control. This is the TRIGGER:IMMediate command. If the trigger subsystem is in the Initiated state, this command generates a trigger that transfers the trigger subsystem directly to the Output Change state, bypassing the Delaying state.

Delaying State
When a trigger event occurs on the selected trigger source, the trigger subsystem transfers to the Delaying state. In this state, the subsystem waits for the interval specified by the TRIGGER:DELay command before moving to the next state. As shown in Figure 5-1A, a TRIGGER:IMMediate command will bypass any programmed delay and cause an immediate transition to the Output Change state.

Figure 5-1. Simplified Models of Trigger Modes
Output Change State
When the trigger subsystem enters the Output Change state, the output voltage and current are set to the pending levels programmed by the `VOLTage:TRIGgered` and `CURRent:TRIGgered` commands. Once this occurs, the existing triggered levels are cleared and must be reprogrammed. If no triggered levels are programmed, then the trigger has no effect on the output levels. When the triggered actions are completed, the trigger subsystem returns to the Idle state.

Model of List Mode Trigger Operation

Figure 5-1B is a simplified model of trigger subsystem operation when power module is programmed for list-mode output. Operation in the Idle, Initiated, and Delaying states are identical to that described under fixed-mode operation.

Output Change State
When the trigger subsystem enters the Output Change state in List mode, the output voltage and/or current is set to the next value (point) in the programmed list. The trigger subsystem then transfers to the next (Dwelling) state and increments the list to the next point. If there are no more points in the list, the subsystem resets the list to the first point. This completes the list, unless `LIST:COUNt` is programmed to greater than one. In that case, the list is not completed until it has repeated the list sequence the number of times specified by the count.

Dwelling State
Each voltage and current list point has an associated dwell interval specified by the `LIST:DWELL` command. After the new output value is established, the trigger system pauses for the programmed dwell interval. During this dwell interval, trigger events are ignored and only an `ABORt` (or implied abort) command can transfer the subsystem out of the Dwelling state.

At the end of the dwell interval, the transition to the next state depends on whether or not the list has completed its sequencing and on how the `LIST:STEP` command has been programmed.

- If the list is completed, the trigger subsystem returns to the Idle state.
- If the list is not completed, then the subsystem reacts as follows:
  - If `LIST:STEP ONCE` has been programmed, the trigger subsystem returns to the Idle state.
  - If `LIST:STEP AUTO` has been programmed, the trigger subsystem returns to the Output Change state and immediately executes the next list point.

The INITiate:CONTinuous Command
In the above descriptions of the trigger subsystem models, the `INITiate:IMMediate` command was used to move from the Idle to the Initiated state. In some applications, it may be desirable to have the subsystem return directly to the Initiated state after a trigger action has completed. Programming `INITiate:CONTinuous ON` does this by bypassing the Idle state. If the `ABORt` command is given while `INIT:CONT` is ON, the trigger subsystem transfers to the Idle state but immediately exits to the Initiated state.

Trigger Status and Event Signals
Some transitions of the trigger subsystem provide inputs to the status subsystem. Others are defined as "event handles", which are selectable trigger sources by way of parameters in link commands `TRIGger:LINK`, `OUTPut:DFI:LINK` and `OUTPut:TTL:LINK` (see Table 3-1). Table 5-1 summarizes these signals.

Trigger In and Trigger Out

The mainframe has two BNC connectors labeled **Trigger In** and **Trigger Out**. Figure 5-2 shows the model for these signals, which are applied to all power modules in the mainframe (see “TrigIn/TrigOut Characteristics” in Chapter 1 of Agilent 66000A Installation Guide for electrical parameters). **Trigger In** and **Trigger Out** are electrically isolated at each power module from the mainframe chassis reference ground.

**Trigger In**

**Trigger In** is a TTL level input that can be selected as a trigger source for each module. Modules recognize a **Trigger In** signal on its falling edge. **Trigger In** is selected as a trigger source with the EXternal parameter. For example:

```
TRIGger:SOURce EXT
OUTPut:TTLT:SOURce EXT
```

**Trigger Out**

The **Trigger Out** signal is a 20-microsecond, negative-true TTL pulse. This pulse can be driven by each power module by programming the OUTPut:TTLT commands. Each module can also select **Trigger Out** as a trigger source by programming the SCPI TRIGger:SOURce TTLT command (see "Chapter 3 - Language Dictionary" for details of these commands).

- To select the **Trigger In** connector as a trigger source, use **TRIGger:SOURce EXT**
- To apply a trigger to the **Trigger Out** connector, use **OUTPut:TTLT ON**. You must also select the source (OUTP:TTLT:SOUR).

![Figure 5-2. TTLT Trigger Model](image-url)
List Subsystem

The List Subsystem commands allow you to program a sequence of voltage and/or current values that will be applied to the power module output when it is the list mode (VOLTage:MODE LIST or CURRent:MODE LIST). Up to 20 voltage and current values, with 20 associated time intervals (dwells), may be programmed. By using lists, you can program a complex sequence of power module outputs with minimal interaction between the controller and the power module. Lists allow you to time output changes more precisely or to better synchronize them (using triggers) with asynchronous events.

Basic Steps of List Sequencing

You can program the number of output levels (or points) in the list, the time interval that each level is maintained, the number of times that the list will be executed, and how the levels change in response to triggers. This is a synopsis of the list commands:

<table>
<thead>
<tr>
<th>List Function</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable the voltage list function</td>
<td>VOLT:MODE LIST</td>
</tr>
<tr>
<td>Enable the current list function</td>
<td>CURR:MODE LIST</td>
</tr>
<tr>
<td>Specify the voltage output levels (points)</td>
<td>LIST:VOLT &lt;NRf+&gt;</td>
</tr>
<tr>
<td>Specify the current output levels (points)</td>
<td>LIST:CURR &lt;NRf+&gt;</td>
</tr>
<tr>
<td>Specify the time duration of each output level</td>
<td>LIST:DWEL &lt;NRf+&gt;</td>
</tr>
<tr>
<td>Specify the times the list is repeated</td>
<td>LIST:COUN &lt;NRf+&gt;</td>
</tr>
<tr>
<td>Select the list response to a trigger</td>
<td>LIST:STEP AUTO</td>
</tr>
</tbody>
</table>

Programming the List Output Levels

1. Enable the specific output to be controlled by the list. For example,
   VOLT:MODE LIST
   CURR:MODE LIST

2. Program the desired output levels or points. The order of the points determines the order in which the output levels will occur. To sequence the voltage through values of 1, 1.5, 3, 1.5, and 1 volts, program:
   LIST:VOLT 1,1.5,3,0,1.5,1
   You can specify lists for both voltage and current. For example:
   LIST:VOLT 1,2,5,6,8
   LIST:CURR 10,5,2,1.67,1.25

Both lists must have the same number of points. The exception is if a list has only a single point. In this case, the single-point list is treated as if it has the same number of points as the other list with each point equal to the programmed value. For example, if you send:
   LIST:VOLT 1,2,5,6,8;CURR 1
   then the power module will respond as if the two lists were:
   LIST:VOLT 1,2,5,6,8
   LIST:CURR 1,1,1,1,1

Note Execution of a list will be aborted if an ABORt command or an implied ABORt command (another list command, the *RST command or the *RCL command) is sent.

Programming List Intervals

The dwell time is the interval that the output remains at the programmed value. The time unit is seconds. The following command specifies five dwell intervals:
   LIST:DWEL 1,1.5,3,1.5,5
The number of dwell points must equal the number of output points:

```
LIST:VOLT 3.0,3.25,3.5,3.75
LIST:DWEL 10,10,25,40
```

The only exception is for a dwell list with one value, which gives the same interval to all the points in the corresponding voltage or current list.

---

**Note**

Sending a `VOLT [: LEV: IMM]` or `CURR [: LEV: IMM]` command during an interval will override the list output value for that interval. When the next interval begins, the output will be determined by the list value for that interval.

---

**Automatically Repeating a List**

You can repeat a list by entering a `LIST: COUN` parameter. The parameter determines how many times a list is executed or sequenced. Enter an integer or enter the value `INF` to make the list repeat indefinitely. For example, to make the current list `2,3,12,15` repeat 5 times, send:

```
LIST:CURR 2,3,12,15
LIST:COUN 5
```

The `LIST: COUN` parameter is stored by `*SAV` and restored by `*RCL`. The GPIB `*RST` value is 1.

---

**Triggering a List**

No list will execute without a trigger. How the list responds to a trigger depends on how you program the `LIST: STEP AUTO | ONCE` command. The method you use will depend upon whether you want the list to be paced by dwell intervals or by triggers.

**Dwell-Paced Lists**

For a closely controlled sequence of output levels, you can use a dwell-paced list. Each list output point remains in effect for the dwell time associated with that point. When the dwell time expires, the output immediately changes to the next point in the list.

For dwell pacing, program `LIST: STEP` to `AUTO` (see Figure 5-3-A). The dwell-paced list requires only a single trigger to start the list. The trigger subsystem remains in the dwelling state until the list is completed. If `LIST: COUN` is greater than 1, the entire list is repeated until the count has been satisfied (see Figure 5-1-B).

**Trigger-Paced Lists**

If you need the output to closely follow asynchronous events, then a trigger-paced list is more appropriate. Program `LIST: STEP` to `ONCE` (see Figure 5-3-B). Now expiration of a dwell interval returns the trigger subsystem to the Initiated state. The subsystem then waits for a trigger to start the next dwell interval. During this time, the power module output remains at the level set by the last executed point in the list.

---

**Note**

If the subsystem is not in the dwelling state, a `TRIGger [: IMMEDIATE]` command will sequence the next point in the list.
Figure 5-3. Timing diagrams of LIST:STEP Operation
DFI (Discrete Fault Indicator) Subsystem

Whenever a fault is detected in the power module, it is capable of generating a low-true TTL signal at the mainframe FLT jack for communication with external devices (see “INH/FLT Characteristics” in Chapter 1 of the Agilent 66000A Installation Guide for the electrical parameters). The source for the DFI signal can be any of the parameters of the `OUTPut:DFI:LINK` command (see Table 3-1). The `SUM3` link parameter allows any combination of Questionable, Operation, or Event status bits to generate the DFI signal. The GPIB `*RST` command sets the link parameter to `SUM3`.

RI (Remote Inhibit) Subsystem

Each power module is connected to the mainframe INH jack via a function selector switch. (See Chapter 2 of the Operating Guide for details concerning this switch.) When the switch is set to enable the RI function, a low-true TTL signal at the INH input will shut down the power module. This generates an RI status bit at the Questionable Status register (see "Chapter 4 - Status Reporting"). By programming the status subsystem, you may use RI to generate a service request (SRQ) to the controller and/or to create a DFI output at the mainframe FLT jack. By using RI/DFI in this way, you can chain the power modules to create a serial shutdown in response to the INH input.

SCPI Command Completion

SCPI commands sent to the power module are processed either sequentially or in parallel. Sequential commands finish execution before a subsequent command begins. A parallel command can begin execution while a preexisting command is still executing (overlapping commands). Commands that affect list and trigger actions are among the parallel commands.

There `*WAI`, `*OPC`, and `*OPC?` common commands provide different ways of indicating when all transmitted commands, including any parallel ones, have completed their operations. The syntax and parameters for these commands are described in "Chapter 3 - Language Dictionary". Some practical considerations for using these commands are as follows:

- **`*WAI`**: This prevents the power module from processing subsequent commands until all pending operations are completed. If something prevents completion of an existing operation, `*WAI` can place the module and the controller in a "hang-up" condition.

- **`*OPC?`**: This places a 1 in the Output Queue when all pending operations have completed. Because it requires your program to read the returned value from the queue before executing the next program statement, `*OPC?` could prevent subsequent commands from being executed.

- **`*OPC`**: This sets the `OPC` status bit when all pending operations have completed. Since your program can read this status bit on an interrupt basis, `*OPC` allows subsequent commands to be executed.

The trigger subsystem must be in the Idle state in order for the status OPC bit to be true. Therefore, as far as triggers and lists are concerned, OPC is false whenever the trigger subsystem is in the Initiated state. However, OPC is also false if there are any commands pending within any other subsystems. For example, if you send `CURR:TRIG 1 . 5` after a `VOLT:LIST` command, completion of the `CURR:TRIG` command will not set OPC if the list command is still executing.

**Note**

For a detailed discussion of `*WAI`, `*OPC` and `*OPC?`, see "Device/Controller Synchronization Techniques" in ANSI/IEEE Std. 488.2-1987.
Error Messages

Power Module Hardware Error Messages
Front panel error messages resulting from selftest errors or runtime failures are described in the power module User’s Guide.

System Error Messages

System error messages are read back via the SYST:ERR? query. The error number is the value placed in the power module error queue. SYST:ERR? returns the error number into a variable and combines the number and the error message into a string. Table 6-1 lists the system errors that are associated with SCPI syntax errors and interface problems. Information inside the brackets is not part of the standard error message, but is included for clarification. When system errors occur, the Standard Event Status register (see "Chapter 4 - Status Reporting") records them as follows:

Application Programs

This section contains seven example applications. For each application, there is:

- An overview of the application.
- Which MPS features are used to implement the application.
- The advantages and benefits of the MPS solution.
- The details of the implementation of the solution.
- A block diagram of the setup.
- A sample program listing in Agilent BASIC.
- A description of variations on the application.

The following table lists what MPS features are used in each of the applications. It can be used as an index into this section.

Application 1. Sequencing Multiple Modules During Power Up

Overview of Application

When testing mixed signal devices, ± bias supply voltages are typically applied before logic bias supply voltages. For a device that is sensitive to when bias voltages are applied, the order of power up of multiple power modules can be controlled.

For this example, the device requires three bias supplies, +5 V for the logic circuits and ±15 V for amplifier circuits. To properly power up the device, the supplies must be sequenced so that the ±15 V are applied first and the +5 V is applied 50 ms later.

The MPS can easily address this application through the use of triggers. The trigger will cause the modules to change from 0 V, where they are not powering the DUT, to their final voltage. By delaying the response to the trigger, you can control when the module's output voltage changes. This means you can control the sequence of the modules during power up.

MPS Features Used

- Change the voltage on trigger.
- Trigger in/out from MPS mainframe backplane TTL Trigger.
- Trigger on a GPIB trigger command Trigger delay.
- Trigger delay.

Advantages/Benefits Of The MPS Solution

By using trigger delay, the timing is accurate and repeatable.
The sequence is simpler to program (no timing loops).
The computer is not devoted to sequencing power modules.
The computer does not provide timing for the sequence.
One command initiates the sequence.

Implementation Details

How the MPS Implements The Sequence

The computer sends a trigger command to the first module.
The first module simultaneously sends a backplane trigger to other two modules and goes to +15 V.
The second module receives the backplane TTL Trigger and immediately goes to -15 V.
The third module receives the backplane TTL Trigger, delays 50 ms, and then goes to +5 V.

MPS Set Up

Module in slot 0:
The module is connected to +15 V on the DUT.
The initial voltage setting is 0 V.
The module listens for the computer to send a trigger command.
Upon receipt of the trigger command, the module goes to 15 V.
Also upon receipt of the trigger command, the module generates a backplane TTL Trigger.

Module in slot 1:
The module is connected to -15 V on the DUT.
The initial voltage setting is 0 V.
The module listens for a backplane TTL Trigger.
Upon receipt of the trigger, the module goes to 15 V.
Module in slot 2:
The module is connected to + 5 V on the DUT.
The initial voltage setting is 0 V.
The module listens for a backplane TTL Trigger.
The trigger delay is programmed to 50 ms.
Upon receipt of the trigger, the module waits the trigger delay time and then goes to 5 V.

Variations On This Implementation

1. The modules could be set to generate SRQ when the last module (+ 5 V) reaches its final output value. This would notify the computer that power has been applied to the DUT and the testing can begin.

2. To provide a delay between the application of the + 15 V and the -15 V bias, you can program different trigger delays into modules 2 and 3. The delay time will be relative to the module in slot 0.

3. To get all three modules to apply power to the DUT at the same time, simply eliminate the trigger delay on the + 5 V module.

4. When modules need to be connected in parallel to increase current, they will also need to be synchronized so that they all apply power simultaneously. To get modules in parallel to apply power at the same time, use the approach described in this example, but eliminate any trigger delays.

Figure B1-3. Agilent BASIC Program Listing for Application #1
Application 2. Sequencing Multiple Modules to Power Down on Event

Overview Of Application

When testing devices, such as some GaAs and ECL devices that are sensitive to when bias voltages are removed, the order of power-down of multiple power modules can be controlled. The power-down sequence can be initiated by an event, such as a change in power module status, fault condition, detection of a TTL signal, etc.

For this example, there are three supplies +5 V and ±15 V. (See previous application for how to generate a power up sequence.) Once the power has been applied to the DUT, the modules can be reprogrammed to perform the power down sequence. The power down sequence is initiated when a fault in the DUT draws excessive current from the power module, causing the module to change from CV to CC. To prevent damage to the DUT, it is necessary to remove the +5 V first, then the ±15 V modules 15 ms later.

Once again, MPS triggering can solve the application. In this scenario, the CV-to-CC crossover event will be used as the trigger source. The trigger will cause the modules, in the correct order, to change from their programmed voltages down to 0 V.

MPS Features Used

- Generate a trigger on a change in internal status.
- Change the voltage on trigger.
- Trigger in/out from MPS mainframe backplane TTL Trigger or Trigger delay.
- Active downprogramming.

Advantages/Benefits Of The MPS Solution

By using the modules' change in status to automatically generate a trigger, the computer is not devoted to polling the modules to detect a change in state.
By letting each module monitor its status, the CC condition will generate a response faster than if the computer was polling the module to detect a change in state.
The sequence is simpler to program (no timing loops).
By using trigger delay, the timing is accurate and repeatable because the computer does not provide timing for the sequence.
The active downprogrammers in the module output can quickly discharge the module's output capacitors and any capacitance in the DUT.

Implementation Details

How The MPS Implements The Solution

All modules are set to listen for a backplane TTL Trigger.
When any module detects a change in status from CV to CC, it sends out a backplane TTL Trigger.
When the +5 V module receives the trigger, it immediately goes to 0 V.
When the +15 V and -15 V modules receive the trigger, they wait the trigger delay time and then go to 0 V.

Note

Any module can generate both the backplane TTL Trigger signal and be triggered by that same signal.
MPS Set Up

Module in slot 0:
The module is connected to $+15\,\text{V}$ on the DUT.
The initial voltage setting is $15\,\text{V}$.
The module monitors its status.
The module will generate a backplane TTL Trigger on CV-to-CC crossover.
The module listens for a backplane TTL Trigger.
The trigger delay is programmed to $15\,\text{ms}$.
Upon receipt of the trigger, the module waits the trigger delay time and then goes to $0\,\text{V}$.

Module in slot 1:
The module is connected to supply $-15\,\text{V}$ to the DUT.
The initial voltage setting is $15\,\text{V}$
The module monitors its status.
The module will generate a backplane TTL Trigger on CV-to-CC crossover.
The module listens for backplane TTL Trigger.
The trigger delay is programmed to $15\,\text{ms}$.
Upon receipt of the trigger, the module waits the trigger delay time and then goes to $0\,\text{V}$.

Module in slot 2.
The module is connected to supply $+5\,\text{V}$ to the DUT.
The initial voltage setting is $5\,\text{V}$.
The module monitors its status.
The module will generate a backplane TTL Trigger on CV-to-CC crossover.
The module listens for backplane TTL Trigger.
Upon receipt of the trigger, the module immediately goes to $0\,\text{V}$.

Variations On This Implementation

1. The modules could be set to generate SRQ when the last module reaches $0\,\text{V}$. This could notify the computer that power has been removed from the DUT.

2. The modules could be set to generate a DFI (Discrete Fault Indicator) signal on the MPS rear panel on a change in status. This signal could be used to shut down other power modules, to flash an alarm light, or to sound a buzzer. This could also be routed to other instruments to signal them to stop making measurements.

3. To get all three modules to remove power from the DUT at the same time, simply eliminate the trigger delay on the $\pm15\,\text{V}$ modules.

4. To provide a delay between the removal of the three bias voltages, you can program a different trigger delay into each module.

OUTPUT @Slot2;"OUTPUT:TTLTRG:STATE ON" ! ENABLE TTL TRIGGER DRIVE
OUTPUT @Slot2;"OUTPUT ON" ! ENABLE OUTPUT

The power modules are now set up to implement the power down on event.

Any time any module goes into CC, the sequence will occur.

END

Figure B2-3. Agilent BASIC Program Listing for Application #2
Application 3. Controlling Output Voltage Ramp Up at Turn On

Overview Of Application

When control over the rate of voltage ramp up at turn-on of the power module output is required, the desired shape can be approximated by downloading and executing a series of voltage and dwell time points.

For this example, you need to program the power module to change its output from 2 volts to 10 volts, slewing through the 8 volt transition in 0.5 seconds. This results in a turn-on ramp-up of 16 V per second.

The MPS can create this voltage versus time characteristic using Lists. The desired characteristic (in this case, linear) is simulated using the 20 available voltage points. To determine the value of each point in the transition, simply divide the change in voltage by 20. To determine the dwell time of each voltage point, divide the total transition time by 19. After the List has been executed, the module will continue to output the final value (in this case, 10 volts) until the output has been reprogrammed to another value. Note that the dwell-time of the last point is not part of the transition time.

To determine the slowest ramp up (longest transition time) that can be generated, you must consider how smooth you need the voltage versus time characteristic to be. As the dwell time associated with each point gets longer, the output voltage will become more like a "stair step" and less like a linear transition. (see Figure B3-1)

To determine the fastest ramp up (shortest transition time) that can be generated, you must consider the minimum dwell time specification (10 ms) and the maximum risetime of specification the power module (20 ms). If you program 10 ms dwell times, the power module will not be able to reach its output voltage before the next voltage point is output. (see Figure B3-2)

MPS Features Used

- 20-point voltage List.
- Dwell time.
- Dwell-paced Lists.

Advantages/Benefits Of The MPS Solution

By using Lists, the module changes its output voltage automatically, so that the computer is not devoted to reprogramming the output voltage.

The outputs can change faster when dwell paced than when the computer must explicitly reprogram each change.

The sequence is simpler to program (no timing loops). By using dwell times, the timing of each point is accurate and repeatable.

The computer does not provide timing for the sequence. For negative-going ramps, the active downprogrammers in the module output can quickly discharge the module’s output capacitors and any capacitance in the DUT when negative going ramps are required.

Implementation Details

How the MPS Implements The Sequence

The module is programmed to List mode.
The module will execute a dwell-paced List.
The 20 voltage points are downloaded to the module.
The 20 dwell times are downloaded to the module.
When the transition must occur, the module is triggered by the computer.
The module output ramps under its own control.
Variations On This Implementation

1. The module could be set to begin ramping in response to an external or backplane TTL Trigger.

2. The module could be set to generate SRQ when it has finished its transition. This would notify the computer that the voltage is at the proper level.
3. The module could be set to generate an external trigger when it has finished its transition. This trigger could be routed to other instruments as a signal to start making measurements.

4. Multiple modules could be programmed to slew together in response to the computer trigger command.

5. The module could be set to generate an external trigger for each point in the transition. This trigger could be routed to other instruments as a signal to take a measurement at various supply voltages. (see application #7)

6. Many voltage versus time characteristics can be generated by varying the voltage values and the dwell times in the List.

Figure B3-4. Agilent BASIC Program Listing for Application #3
Application 4. Providing Time-Varying Voltages

Overview of Application

To burn-in devices using thermal or mechanical cycling/stress, cyclical time-varying voltage is provided by programming a set of voltage and dwell time points that repetitively sequence over time.

For this example, the power module must provide the repetitive waveform shown in Figure B4-1. This time-varying voltage will be applied to a hybrid IC. By continually cycling the voltage from 0 to 7 volts over a 33 second interval, the hybrid is given time to heat up and undergo thermal and mechanical stress as the welds inside the hybrid expand and contract, and then subsequently cool down.

In addition to generating the cyclical voltage, it is desirable to have the power module notify the computer should the device fail and stop the cycling. Since the module is monitoring test status, the computer is free to perform other tests.

The MPS can address this application using dwell-paced repetitive Lists. This application could be thought of as a simple power arbitrary waveform generator. To get the desired time-varying voltage, you must be able to describe the waveform in 20 discrete voltage points, with each point ranging from 10 ms to 65 seconds. This range of dwell times determines the range of frequencies (or time rate of change) of the voltage waveform to be generated.

Once the waveform has been described, it is downloaded to the module. Upon being triggered, it will repetitively generate the waveform without computer intervention.

The module will also be set up to generate an SRQ and stop the voltage cycling of the hybrid should fail. If the hybrid fails by shorting, the module will go into CC. This change in status will cause the module to protect the DUT by disabling the output, which will stop the test and generate an SRQ. (Open circuit failures will not be detected. Since failures of this type are less likely to have destructive consequences, detection is not required.)
**MPS Features Used**

- 20-point voltage List.
- Repetitive Lists.
- Dwell time.
- Dwell-paced Lists.
- Generate an SRQ on a change in internal status.
- Disable the output on a change in internal status.
- Stop the List on a change in internal status.
- Trigger on a GPIB trigger command.
- Overcurrent protection.
- Active downprogramming.

**Advantages/Benefits Of The MPS Solution**

By using Lists, the module changes its output voltage automatically, so that the computer is not devoted to reprogramming the output voltage.
The output can change faster when dwell paced than when the computer must explicitly reprogram each change.
Overcurrent protection can disable the output before the DUT is damaged.
By letting each module monitor its status, the CC condition will be responded to faster than if the computer was responsible for stopping the test.
The sequence is simpler to program (no timing loops),
By using dwell times, the timing of each point is accurate and repeatable because the computer does not provide timing for the sequence.
When the output is disabled, the active downprogrammers in the module output can quickly discharge the module’s output capacitors and any capacitance in the DUT.

**Implementation Details**

**How The MPS Implements The Sequence**

The module is programmed to List mode.
The module will execute a dwell-paced List.
The 3 voltage points are downloaded to the module.
The 3 dwell times are downloaded to the module.
To begin the cycling, the module is triggered by the computer.
The module continuously generates the voltage waveform.
The module continuously monitors its status.
If the module goes into CC, the overcurrent protection disables the output.
The module generates an SRQ when the overcurrent protection occurs.

**Module set up**

Set voltage mode to List.
Download voltage List.
Download dwell times.
Set Lists to dwell paced.
Set Lists to infinitely repeat.
Enable status monitoring of overcurrent condition.
Enable overcurrent protection.
Enable SRQ generation on overcurrent protection occurrence.
Variations On This Implementation

1. The module could be set to begin generating the waveform in response to an external or backplane TTL Trigger.

2. The module could be set to generate external triggers for each point in the List. This trigger could be routed to other instruments to synchronize external measurements to the change in voltage. (see application #7) Using this technique, parametric measurements could be made on the device during the thermal cycling.

3. Multiple modules could be programmed to cycle together in response to the computer trigger command.

4. To determine how many times the hybrid was cycled before it failed, you can use the SRQ (that was generated when the hybrid failed and the module went into CC) to timestamp the failure. The elapsed time will give the number of cycles executed.

---

Figure B4-2. Agilent BASIC Programming Listing for Application #4
Application 5. Providing Time-Varying Current Limiting

Overview Of Application

To provide current limit protection which varies as a function of time, multiple thresholds on current limit are required. Having multiple thresholds can provide a high limit to protect the DUT during its power-up in-rush with automatic switchover to a lower limit to protect the DUT during its steady state operation.

For this example, the DUT is a printed circuit assembly. This assembly is being tested prior to installation in the end product. The module provides power to the assembly, which will undergo a functional test. The assembly has capacitors on-board, and when power is applied, the in-rush current approaches 4 A. After the capacitors charge, which takes about 500 milliseconds, the steady state current settles to 600 mA. See Figure B5-1.

The MPS can address this application using dwell-paced Lists. In this case, the List will consist of a set of current limits and dwell times, because the voltage will remain constant throughout the test.

Once power has been applied, the first current limit, which provides protection to a shorted DUT while still allowing high current in-rush to occur, will remain in effect for the dwell time. Then the current limit will switch to its next setting in the List. The result is a current limit which changes with time and provides protection as the DUT current requirements drop off to their steady state value. When the dwell time expires for the last current limit in the List, the current limit stays at this value until reprogrammed. Thus, the actual value of the last dwell time is not important. The last current List point would be the current limit for the steady state operation during the test of the DUT. See Figure B5-2 for how the MPS implements this protection.

Throughout List execution, overcurrent protection will be enabled. If at any time the module goes into CC, the output will be disabled, the test stopped, and the DUT protected.

MPS Features Used

- 20-point current List.
- Dwell time.
- Dwell-paced Lists.
- Disable the output on a change in internal status.
- Stop the List on a change in internal status.
- Change the voltage on trigger.
- Trigger on a GPIB trigger command.
- Overcurrent protection.
- Active downprogramming.

Advantages/Benefits Of The MPS Solution

By using Lists, the module changes its current limit automatically, so that the computer is not devoted to reprogramming the current limit.

The output can change faster when dwell paced than when the computer must explicitly reprogram each change.

Overcurrent protection can disable the output before the DUT is damaged.

By letting the modules monitor status, the CC condition will be responded to faster than if the computer was responsible for stopping the test.

The sequence is simpler to program (no timing loops).

By using dwell times, the timing of each point is accurate and repeatable because the computer does not provide timing for the sequence.

When the output is disabled, the active downprogrammers in the module output can quickly discharge the module’s output capacitors and any capacitance in the DUT.
Figure B5-1. Typical DUT Current vs. Time

Figure B5-2. Desired Current vs. Time
Implementation Details

How The MPS Implements The Sequence.

The module is programmed to current List mode.
The module will execute a dwell-paced current List.
The current limit List points are downloaded to the module.
The dwell times are downloaded to the module.
To begin powering the DUT, the module is triggered by the computer. This one trigger causes the current List to begin
executing and the voltage to go to its programmed value.
The module steps through the current limit List.
The module continuously monitors its status.
If the modules goes into CC, the overcurrent protection disables the output.

Module Set Up

Set the current mode to List.
Download current List.
Download the dwell times.
Set the List to be dwell paced.
Enable overcurrent protection.
The initial voltage setting is 0 V.
The module listens for the computer to send a trigger command.
Upon receipt of the trigger command, the module goes to 12 V.
Also upon receipt of the trigger command, the module begins executing its current limit List.

Variations On This Implementation

1. The module could be set to begin applying power in response to an external or backplane TTL Trigger.

2. Multiple modules could be programmed to cycle together in response to the computer trigger command. Each module
could have unique current limits, voltage settings, and dwell times.

3. The module could be set to generate an SRQ if the overcurrent protection disables the output.

4. The module could be set to generate an external or backplane TTL Trigger if the overcurrent protection disables the
output.

5. The in-rush current can be controlled using the current limit settings of the current List. Instead of setting the current
limit slightly above 4 A, it could be set at a much lower value. This would limit the in-rush current to the value in the
List. It would take longer to charge the capacitors on the assembly, but the inrush condition would be controlled. In this
variation, the overcurrent protection could not be used, because you want the module to be in CC.

Figure B5-3. Agilent BASIC Program Listing for Application #5
Application 6. Output Sequencing Paced by the Computer

Overview Of Application

When performing bias supply margin testing, throughput can be maximized by eliminating the command processing time associated with reprogramming all outputs for each set of limit conditions. Instead, multiple sets of bias limit conditions can be downloaded to the power modules during test system initialization. During the testing, the computer can use a single command to simultaneously signal all power modules to step through each test condition.

In this example, the DUT requires + 5 V and ± 12 V. The DUT is tested to ensure proper operation at marginal supply voltages. The margin specified is ± 5 % of nominal voltage. At each of the combinations given below, the computer first sets up the three modules and makes a measurement on the DUT. The combinations to be tested are:

<table>
<thead>
<tr>
<th>Nominal 5 V</th>
<th>Nominal + 12 V</th>
<th>Nominal - 12 V</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.75 V</td>
<td>12 V</td>
<td>-12 V</td>
</tr>
<tr>
<td>5 V</td>
<td>12 V</td>
<td>-12 V</td>
</tr>
<tr>
<td>5.25 V</td>
<td>12 V</td>
<td>-12 V</td>
</tr>
<tr>
<td>5 V</td>
<td>11.4 V</td>
<td>-12 V</td>
</tr>
<tr>
<td>5 V</td>
<td>12.6 V</td>
<td>-12 V</td>
</tr>
<tr>
<td>5 V</td>
<td>12 V</td>
<td>- 11.4 V</td>
</tr>
<tr>
<td>5 V</td>
<td>12 V</td>
<td>- 12.6 V</td>
</tr>
</tbody>
</table>

When conducting this test, the modules will need to be reprogrammed 21 times and seven measurements made. The command processing time could slow down this test.

The MPS can be used to increase throughput. By downloading all of the combinations into the three modules, each setting can be quickly stepped through by triggering all modules to change to their next voltage setting and then taking a measurement from the DUT. This permits testing without command processing overhead.

MPS Features Used

- 20-point voltage List.
- Trigger-paced Lists.
- Trigger in/out from MPS mainframe backplane TTL Trigger.
- Trigger on a GPIB trigger command.

Advantages/Benefits Of The MPS Solution

By using Lists, the module changes its voltage without delays due to processing the command to change the output voltage. By using triggers, all three outputs can be changed with one command.

The computer loop to change the settings and take a measurement is simplified, because you do not have to explicitly reprogram each module output. Instead, the loop becomes "Trigger" and "Measure".

Implementation Details

How The MPS Implements The Sequence

The following steps are performed for each point in the List:
The computer sends a trigger command to the first module.
The first module simultaneously sends a backplane TTL Trigger to the other two modules and goes to its next List point.
The second module receives the backplane TTL Trigger and immediately goes to its next List point.
The third module receives the backplane TTL Trigger, immediately goes to its next List point.
The computer gets a measurement from the measurement instrument.
MPS Set Up

Module in slot 0:
The module is connected to + 5 V on the DUT.
The initial voltage setting is 0 V.
Set the voltage mode to List.
Download the voltage List.
Set the List to be trigger paced.
The module listens for the computer to send a trigger command. Upon receipt of the trigger command, the module outputs its next List point.
Also upon receipt of the trigger command, the module generates a backplane TTL Trigger.

Module in slot 1:
The module is connected to + 12 V on the DUT.
The initial voltage setting is 0 V.
Set the voltage mode to List.
Download the voltage List.
Set the List to be trigger paced.
The module listens for a backplane TTL Trigger.
Upon receipt of a trigger, the module goes to its next List point.

Module in slot 2.
The module is connected to -12 V on the DUT.
The initial voltage setting is 0 V.
Set the voltage mode to List.
Download the voltage List.
Set the List to be trigger paced,
The module listens for a backplane TTL Trigger.
Upon receipt of a trigger, the module goes to its next List point.

Variations On This Implementation

1. A current List could also have been executed by the module so that for each voltage point, a corresponding current limit could be programmed.

2. Overcurrent protection could be enabled to protect a faulty DUT.

3. The module could generate an SRQ when it finishes changing voltage for each point in the List based on the STC (Step Completed) status bit, which indicates when the module has completed executing the next point in the List. The SRQ could tell the computer to get a measurement from the measurement instrument.

4. The module could be told to output its next List point in response to an external or backplane TTL Trigger. (see next application.)

Figure B6-3. Agilent BASIC Program Listing for Application #6
Application 7. Output Sequencing Without Computer Intervention

Overview Of Application

When characterizing devices, the DUT’s performance is measured over a range of power supply voltages. This test can be performed without computer intervention by using hardware signals from the measurement instrument to cause the power module to sequence to the next voltage in a preprogrammed List. By buffering these readings in the measurement instrument, the entire test can be executed without computer involvement. For characterizations that require long measurement times, the computer is free to do other tasks. For characterizations that must execute at hardware speeds, the computer is not involved and will not slow down the test loop.

In this example, the power module must apply 8 to 14 volts (in 13 0.5-volt increments) to an automotive engine sensor. The module varies the bias voltage to the engine sensor and the sensor’s output is measured to characterize its performance over the range of possible “battery voltages”. The sensor output is measured by a DMM that has an internal buffer and stores each reading.

By combining Lists and trigger capabilities, the MPS can be used to address this application. The module can be programmed to use its triggering capabilities to the fullest extent. Each time the module executes the next step in its List and changes voltage, the module will generate an external trigger. The external trigger will cause the DMM, equipped with an external trigger input, to take and store a reading. The DMM, also equipped with a “Measurement Complete” output, sends its output trigger signal to the module to tell the module to go to its next List point. Effectively, the module and the DMM “handshake”, so that the two function at hardware speeds without computer intervention.

When the test is complete, either device can signal the computer to get the data from the DMM. For the purpose of this example, the module will generate an SRQ when the last List point has been executed. This is indicated by the OPC (Operation Complete) bit in the status register.

Another detail that needs attention is timing. The DUT may require some settling time before the DMM is told to take a reading. The module’s dwell time can be used to do this. The STC (Step Complete) status signal indicates when the point has been executed and its dwell time has expired. The dwell time is programmed to be the engine sensor’s settling time. The external trigger is generated when STC is asserted. Thus, the DMM will not be triggered until the dwell time has expired and the sensor’s output has settled.

This type of self-paced test execution is useful in two situations. When the test must execute very fast, there is no time for the computer to be involved in each iteration of the test loop. Therefore, the test must execute without computer intervention. The second situation is when the test is very long. For example, if the measurement instrument took 1 minute to make each measurement, the test would take 13 minutes to execute. The computer is not used efficiently if it is idle while waiting for each measurement loop, so it would be best to have the computer executing another task. Without self-pacing, you would need to develop interrupt driven software that stops every 1 minute to take a reading. By letting the module and the DMM run on their own, code development is much simpler and computer resources are used more efficiently.

MPS Features Used

- 20-point voltage List.
- Dwell time.
- Trigger-paced Lists.
- Generate an SRQ on a change in internal status.
- Generate a trigger on a change in internal status.
- Trigger in/out from MPS mainframe backplane TTL Trigger.
- Trigger on a GPIB trigger command.
Advantages/Benefits Of The MPS Solution

The entire test executes without computer involvement, the command processing time is eliminated from the test loop. The entire test executes without computer involvement, so the computer can perform other tasks while the test executes. Software development is simplified; you do not need to write a test loop because the module and the DMM are running on their own.
By using dwell times, the trigger out signal can be sent at the correct time, which permits the DUT to settle before a reading is taken.

Implementation Details

How The MPS Implements The Sequence

The module listens for the computer to send a trigger command.
Upon receipt of the trigger command, the module outputs its first List point.
After the dwell time expires, the STC is asserted and the module generates an external trigger.
The DMM receives the external trigger, takes and stores a reading.
The DMM generates a "Measurement Complete" output signal when it’s done.
The module receives the DMM output signal as an external trigger in.
Also upon receipt of the trigger in, the module outputs its next List point.
The process repeats for each List point.
After the last List point has executed, the module generates SRQ, telling the computer the test has completed.

MPS Set Up

Set the voltage mode to List.
Download the voltage List.
Download the dwell time List.
Set the List to be trigger paced.
Set the trigger source to external trigger.

Note: The computer trigger command "TRIGGER:IMMEDIATE" is always active, even if the external trigger is the selected source.

Set the module to generate a backplane TTL Trigger on STC. This backplane TTL Trigger drives external trigger out.
Set the module to generate SRQ on OPC.

Variations On This Implementation

1. A current List could also have been executed by the module so that for each voltage point, a corresponding current limit could be programmed.

2. Overcurrent protection could be enabled to protect a faulty engine sensor.

3. If the DMM does not have an internal buffer, the computer could take a reading on each iteration of the test loop (see previous application).

Figure B7-3. Agilent BASIC Program Listing of Application #7
Supplemental Information

This appendix contains program listings translated into the following DOS-compatible languages and GPIB interfaces:

- GWBASIC and the Agilent 61062/82990/82335A GPIB Command Library for MS-DOS
- GWBASIC and the National Instruments GPIB-PC Interface Card
- Microsoft C and the Agilent 61062/82990/82335A GPIB Command Library for MS-DOS
- Microsoft C and the National Instruments GPIB-PC Interface Card

Each program is translated from the Agilent BASIC listing found in application #3. This example program was chosen as representative of all application programs because it shows how to:

- Configure the interface card.
- Address the power module.
- Write strings to the power module.
- Write real arrays to the power module.
- Receive real numbers from the power module.

The six other application programs all use a subset of the above functions.

Agilent Sales and Support Offices

For more information about Agilent Technologies test and measurement products, applications, services, and for a current sales office listing, visit our web site: http://www.agilent.com/find/tmdir

You can also contact one of the following centers and ask for a test and measurement sales representative.

**United States:**
Agilent Technologies
Test and Measurement Call Center
P.O. Box 4026
Englewood, CO 80155-4026
(tel) 1 800 452 4844

**Canada:**
Agilent Technologies Canada Inc.
5150 Spectrum Way
Mississauga, Ontario
L4W 5G1
(tel) 1 877 894 4414

**Latin America:**
Agilent Technologies
Latin American Region Headquarters
5200 Blue Lagoon Drive, Suite #950
Miami, Florida 33126
U.S.A.
(tel) (305) 267 4245
(fax) (305) 267 4286

**Europe:**
Agilent Technologies
Test & Measurement European Marketing Organisation
P.O. Box 999
1180 AZ Amstelveen
The Netherlands
(tel) (31 20) 547 9999

**Australia/New Zealand:**
Agilent Technologies Australia Pty Ltd
347 Burwood Highway
Forest Hill, Victoria 3131
(tel) 1-800 629 485 (Australia)
(fax) (61 3) 9272 0749
(tel) 0 800 738 378 (New Zealand)
(fax) (64 4) 802 6881

**Asia Pacific:**
Agilent Technologies
24/F, Cityplaza One, 1111 King’s Road,
Taikoo Shing, Hong Kong
tel: (852)-3197-7777
fax: (852)-2506-9284

Manual Updates

The following updates have been made to this manual since the print revision indicated on the title page.

4/15/00

All references to HP have been changed to Agilent.
All references to HP-IB have been changed to GPIB.
Information about VXIPlug&Play instrument drivers has been added to chapter 1.
