Introduction

A built-in HP Instrument BASIC (IBASIC) controller (option 1C2) can be ordered with the analyzer. An upgrade (HP model no. 86224B) is also available to add the controller to an analyzer that was not purchased with this option.

This manual describes creating and using IBASIC software on the analyzer. It demonstrates how to use IBASIC's programming, editing and debugging features. It also describes how to save and recall programs and how certain instrument-specific IBASIC features are implemented in the analyzer.

The reader should become familiar with the operation of the analyzer before programming it. This manual introduces the IBASIC operating and programming environment and provides examples of intermediate and advanced IBASIC programs. It assumes familiarity with the analyzer and HP BASIC.

Related information can be found in the following references. Contact a Hewlett-Packard sales or service office if you wish to order any of these documents. A list of HP sales and service offices can be found in the "Specifications" chapter of your User's Guide.

- Information on the IBASIC language, including keyword descriptions, error messages, interface specifics and programming techniques is available in the HP Instrument BASIC Users Handbook.

- Information on operating the analyzer is available in the analyzer's User's Guide.

- Information on programming the analyzer, including example programs, is available in the analyzer's Programmer's Guide.

- Information on the analyzer's HP-IB command mnemonics is also available in the analyzer's Programmer's Guide.

- Information on the SCPI (Standard Commands for Programmable Instruments) programming language is available in A Beginners Guide to SCPI.

- Information on using the HP-IB is available in the Tutorial Description of the Hewlett-Packard Interface Bus.
Overview of HP Instrument BASIC

When installed in your analyzer, HP Instrument BASIC (IBASIC) can be used for a wide range of applications, from simple recording and playback of measurement sequences to remote control of other instruments. IBASIC is a complete language with over 200 keywords.

IBASIC is a complete system controller residing inside your analyzer. It communicates with the analyzer via HP-IB commands over an internal interface bus (select code 8). It can also communicate with other instruments, computers, and peripherals using the external HP-IB interface (select code 7) or the serial (select code 9) or parallel (select code 15) I/O ports.

Note

The analyzer can also be controlled by an external controller. It has a factory default external HP-IB address of 16. When using IBASIC to control other instruments, no other device should use the same address.

The external HP-IB address can be changed using either the front panel keys under the [SYSTEM OPTIONS] HP-IB menu, or the SCPI mnemonic "SYST:COMM:GPIB:ADDR".

Using HP Instrument BASIC

You need not be proficient in a programming language to successfully use HP Instrument BASIC (IBASIC). In keystroke recording mode, IBASIC automatically builds an executable program by capturing measurement sequences as they are performed. With little or no editing of these program lines, you can immediately put your program to work controlling and automating your analyzer.

IBASIC’s programming interface includes an editor. Softkeys are available to allow you to run or continue a program or configure the display.

The IBASIC command set is a subset of the command set of HP BASIC. In fact, IBASIC programs can be run on any HP BASIC workstation with very few changes. When an external PC keyboard (with a DIN connector) is connected to the analyzer, the IBASIC user interface emulates the user interface of the HP BASIC. The PC keyboard can be used for command entry, editing and program inputs.

Using IBASIC, you can:

- Create on screen graphics
- Control other instruments and peripherals
- Create interactive prompts
- Simplify keystrokes with the [BEGIN] key
- Keystroke record programs
- Run applications

IBASIC also works in conjunction with an external controller which can download and run programs, query variables and respond to Service Requests (SRQs).
**Typographical Conventions**

The following conventions are used in this manual when referring to various parts of the HP Instrument BASIC and analyzer operation environments:

<table>
<thead>
<tr>
<th>HARDKEY</th>
<th>The name of a hardkey on the front panel of the analyzer. This notation is also used to represent keys on an external keyboard connected to the analyzer's DIN interface.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Softkey</td>
<td>The label of a softkey.</td>
</tr>
<tr>
<td>Softkey ON/off</td>
<td>Upper case selection in a softkey indicates the state AFTER the softkey is pressed.</td>
</tr>
<tr>
<td>HARDKEY Softkey 1</td>
<td>A series of hardkeys and softkeys represents the path to a given softkey or menu.</td>
</tr>
<tr>
<td>Softkey 2</td>
<td></td>
</tr>
<tr>
<td>&lt;element&gt;</td>
<td>Angle brackets are used to signify a syntax element in a statement.</td>
</tr>
</tbody>
</table>
Recording Programs

IBASIC programs for the analyzer can be created from the instrument's front panel using an external PC keyboard (option 1CL) on an HP controller running HP BASIC, or on a workstation or PC using a text editor.

Keystroke recording, described in this chapter, is ideal for creating simple programs or measurement sequences for instrument control. If a program requires data processing, decision making, or prompts for an operator or graphical setup diagrams, these must be entered using another technique. Alternative methods of program development may be used to supplement keystroke recording and create more sophisticated programs. These methods are covered in Chapter 5, “Developing Programs”.

Keystroke Recording

Of all the available methods of creating IBASIC programs, keystroke recording is by far the easiest. It requires only a couple of steps to set up and run, and can be accomplished with very little knowledge of programming.

What is Keystroke Recording?

Keystroke recording is a way to automatically create IBASIC measurement sequence programs. To enable recording, simply press [SYSTEM OPTIONS] IBASIC Key Record ON off. Then press the normal key sequences of a measurement on the analyzer. Press [SYSTEM OPTIONS] IBASIC Key Record on OFF to terminate the recording. The resulting program can then be run by pressing Run in the [SYSTEM OPTIONS] IBASIC menu.

IBASIC programs communicate with the analyzer over an internal bus. They use the same set of commands used by external controllers for remote operation of the instrument. Keystroke recording works by finding the bus command, called a SCPI mnemonic, that fits each operation performed from the front panel and then building a program line to perform that operation when executed. All program lines built by keystroke recording are entered into the analyzer's program buffer. If the buffer contains no existing lines, a complete executable program will be created. If there is a program in the buffer when recording is turned on, the recorded statements are simply inserted into the existing program. Refer to Chapter 5, “Developing Programs,” for a description of how to record into existing programs.
**IBASIC Programs and the HP-IB Buffer**

Recorded programs work by sending HP-IB commands to the instrument.  

These commands are queued into an input buffer by the instrument. An IBASIC program generally outputs the commands much faster than the instrument can execute them. This often causes the program to complete while the instrument is still executing commands in the input buffer. The instrument continues processing these commands until the buffer is empty.

This may have some side-effects if you are not aware of this interaction. For example, it may not be immediately obvious that the program has actually finished, since the instrument is still functioning "remotely." This could cause confusion if you try to pause and continue a program that has actually completed.

You can clear the buffer from within your program by inserting the statement CLEAR 8 at the beginning of your program (see Chapter 5 for information on editing programs).

Another side-effect of the speed with which the analyzer processes commands is that it is possible for a command to execute before a previous command has completed execution. The most common example of this is a data query that executes before a measurement sweep is complete. This interaction can lead to erroneous data being collected. For more information on synchronizing the execution of commands, refer to “Synchronizing the Analyzer and a Controller” chapter in the *Programmer’s Guide*.

---

**What’s in a Recorded Program**

If you look at any program created using keystroke recording you will find that it is composed of three fundamental IBASIC statements: ASSIGN, OUTPUT and END. The following simple program demonstrates these statements:

1. ASSIGN Rfna TO 800
2. OUTPUT Rfna;"SOUR1:POW -10 dBm"
3. END

The ASSIGN and END statements are automatically created when keystroke recording is used to create a new program (as opposed to modifying an existing one).

There will only be one ASSIGN statement at the beginning of a program and one END statement at the end, but in a typical program there will be many OUTPUT statements. Since the OUTPUT statement does the actual work of controlling the analyzer, let’s take a closer look at how it is used.

---

**Note**

The ASSIGN statement, which is automatically created, will vary depending on the model of analyzer you have:

- HP 8711A,B  ASSIGN @H8711 TO 800
- HP 8712B  ASSIGN @H8712 TO 800
- HP 8713B  ASSIGN @H8713 TO 800
- HP 8714B  ASSIGN @H8714 TO 800

---

2-2 Recording Programs
The OUTPUT Statement

The IBASIC statement

```
OUTPUT <destination>; <data>
```

tells the internal computer to send some information `<data>` to a device at a specific address `<destination>`. The destination can be a device selector number (example: OUTPUT 800), or a name representing a number, called a path name (example: OUTPUT @Rfna). The data can take several forms but in recorded IBASIC programs it is a string containing commands for the instrument (a mnemonic).

Although the OUTPUT command is very flexible it is used only one way when generated by a recording. The following represents a typical OUTPUT command from a recording session:

```
OUTPUT @Rfna;"SOUR1:POW -10 dBm"
```

Notice that the OUTPUT command is followed by a name representing a device selector (@Rfna), followed by a semicolon and the data ("SOUR1:POW -10 dBm").

The ASSIGN Statement

The destination in an OUTPUT statement specifies the address of the device. In recorded programs this address is represented by the I/O path name @Rfna. The following line appears in all recorded programs before any OUTPUT statements:

```
ASSIGN @Rfna to 800
```

The ASSIGN statement allows you to substitute an I/O path name (a variable preceded by the @ symbol) for a device selector number. Therefore, after the above ASSIGN statement, the program line

```
OUTPUT @Rfna;"SOUR1:POW -10 dBm"
```

is equivalent to

```
OUTPUT 800;"SOUR1:POW -10 dBm"
```

The device selector 800 specifies the host instrument as the destination of any data sent by the OUTPUT command. The program communicates with the analyzer via select code 8, the internal HP-IB interface, which is only used for communication between IBASIC programs and the analyzer. The analyzer will respond to any address on the internal interface from 800 to 899 (800 is typically used).

SCPI Mnemonics

The data sent to the analyzer by the OUTPUT command is called a SCPI (Standard Commands for Programmable Instruments) mnemonic and is found in quotes following the device selector path name and semicolon:

```
OUTPUT @Rfna;"SOUR1:POW -10 dBm"
```

SCPI is a standard instrument control programming language providing commands that are common from one product to another, reducing the number of “device specific” commands. It
uses easy to learn, self explanatory syntax that provides flexibility for both novice and expert programmers.

The SCPI mnemonic codes used by IBASIC are the same ones used to control the instrument remotely via an external computer. External computers communicate with the analyzer over the external HP-IB bus while IBASIC programs communicate with it over the internal bus. In our example, the mnemonic "SOUR1:POW -10 dBm" tells the instrument to set the source power to -10 dBm.

For more information on HP-IB interfacing using IBASIC refer to Chapter 8, "Interfacing with the HP-IB." The SCPI mnemonics for the analyzer are documented in the Programmer's Guide.

---

**How Recording Works**

To fully understand IBASIC recording, it is important to understand the relationship between front panel instrument operation and the program that is generated to emulate that operation.

---

**Note**

SCPI mnemonics entered in a program during a recording session do not have a one-to-one correlation with the actual keys that are pressed during that session.

---

The fact that the generated SCPI mnemonics do not exactly correspond to the keys actually pressed is important to remember. As you press a sequence of keys to perform an operation, the corresponding SCPI mnemonic for that operation is generated. The operation may take one keystroke or several, but the mnemonic is not generated until after a valid sequence of keystrokes is completed.

In other words, it is the functional operation of the instrument that is recorded as a mnemonic, not the keystrokes that it takes to perform that operation.

For example, recording the simple key sequence: \[\text{POWER Level \[10\] Enter}\] requires six keystrokes and produces only one mnemonic, "SOUR1:POW -10 dBm", which is generated after the sequence is completed. This is then automatically formed into the command:

```
OUTPUT O[ touching; "SOUR1:POW -10 dBm"
```

and inserted into the program.

This means that if you accidentally press the wrong key in a sequence, it may not show up in the recorded program. Additionally, you cannot exactly mimic keystrokes to leave the instrument in a specific front panel state, unless it is a state that appears as a natural consequence of a completed operation.

As shown in the above example, pressing the \[\text{POWER}\] hardkey in a recording session has the effect of bringing up the \[\text{POWER}\] menu, but does not, by itself, generate a program line. You could not therefore leave the instrument with the \[\text{POWER}\] menu displayed.

---

**2-4 Recording Programs**
Operations That Do Not Record

Although keystroke recording works automatically in most situations, there are some operations that cannot be captured or can only be partially captured using this method. These generally fall into one of the following areas:

- Front panel operations with no corresponding SCPI mnemonic (such as transitional key sequences).
- IBASIC front panel operations (such as some of the softkey operations found under the SYSTEM OPTIONS IBASIC menu).
- Operations requiring additional programming steps (such as passing control of the HP-IB to the instrument for hardcopy output).
- HP-IB operations with no front panel equivalent (such as HP-IB query commands or data transfer).
- Service menu keys (in general)

**Note**
Do not recall programs in keystroke record mode; doing so will overwrite previously recorded program steps.

Front Panel Operations Without Mnemonics

There are some areas of front panel operation which have no corresponding SCPI mnemonics.

- Most operations on the front panel that require numeric entry allow you to use the knob to increment or decrement the current value. This will not record as a program line. You must always use the numeric keypad or step keys to enter any value if you want the operation to be recorded.
- During a measurement sequence it may take several key presses to cause an operation that will generate a mnemonic. The transitional sequences between actual instrument events are not recordable. For example: pressing the [SCALE] key displays the scale numeric entry, but nothing is recorded until you enter a value for the scale parameter.
- Any default states you setup prior to recording or encounter while recording (and consequently do not select) are not recorded.
- Use of step keys are not recommended because the results may depend on the function's step size, which may change as other parameters change.

**Note**
Instrument states that are not specifically selected or changed are not recorded.

Since these default states are not recorded, you must either actively select them to generate a program statement or make sure the instrument is in the same exact state when the program is run as when it was recorded. This is discussed further in the “Avoiding Recording Errors” section of this chapter.
HP Instrument BASIC Operations

Some softkeys under the SYSTEM OPTIONS IBASIC menu cannot be recorded. Operations on programs, such as Run, Continue, Edit and SAVE RECALL Programs, do not record. You can, however, record display partitions and all other save and recall operations not having to do with IBASIC programs.

Although IBASIC operations cannot be recorded, many do have corresponding SCPI mnemonics that allow an external controller to control and communicate with internal IBASIC programs. For more information refer to Chapter 8, “Interfacing with the HP-IB.”

Operations Requiring Additional Programming

Some operations that work well when performed from the front panel have circumstances that require special attention when used in a program. This is due to two kinds of problems, synchronization and active control.

Synchronization

Timing and synchronization must always be anticipated where one event must complete before another can occur. One example of this is when you need to detect a state in the instrument before issuing the next command. For example, suppose you want your program to perform a limit test on data, but only after a sweep has been completed. You can record the command to perform the limit test by pressing key sequences. However, to detect when the instrument has completed a sweep, you must edit the program and include a routine that waits for a status register to indicate the end of the sweep.

Note

Synchronization is only a problem with overlapped commands (such as the command to trigger a sweep), that is commands that don’t hold off the processing of subsequent commands. The analyzer adds an extra command *WAI when an overlapped command is created using keystroke recording. *WAI prevents the analyzer from executing any further commands until the overlapped command has finished. For more information on synchronization see the “Synchronizing the Analyzer and a Controller” chapter in the Programmer’s Guide.
Active Control of the HP-IB Interface

Some operations require the analyzer to be the active controller on the external HP-IB bus. This generally means that the analyzer must be the System Controller (or active control must be passed to it from an external controller, if one is connected). When an IBASIC program begins running, however, the instrument’s active control of the external interface is automatically passed to the program, so active control must be passed back to the analyzer before these operations can be performed.

These operations include all of the following actions when they are directed to HP-IB devices. Note that active control of the HP-IB interface is only a problem if that bus is being used. Hardcopy output to devices on the serial or parallel ports do not require control of the HP-IB.

- **HARD COPY** Start
- **HARD COPY** Abort
- **SAVE RECALL** Select Disk External
- **SAVE RECALL** Save State or Re-Save State (to external disk)
- **SAVE RECALL** Recall State (from external disk)
- **SAVE RECALL** Save ASCII Save Chan 1 or Save Chan 2 (to external disk)

You can keystroke record any of these operations but you will not be able to successfully run the program that is generated. You will need to enter the program lines necessary to first pass control to the analyzer and then wait for control to be passed back to the program.

See the “Passing and Regaining Control” section of Chapter 8 for an example of passing control to the analyzer.

Mnemonics With No Corresponding Front Panel Operation

Several of the analyzer SCPI mnemonics for the instrument perform operations that are not available from the front panel and which, therefore, cannot be recorded. These include operations such as querying instrument status, transferring data over HP-IB, setting and clearing status registers and general HP-IB housekeeping.

These operations are useful for the more advanced HP-IB programmer using IBASIC. Because they fall outside the direct operating realm of the analyzer, they cannot be recorded. They can be added to a recorded program using the built-in editor or another editing environment. See the *Programmer’s Guide* for a complete description of the analyzer’s HP-IB command set. See also “Built-In High Speed Subprograms” in Chapter 9.
Avoiding Recording Errors

Use Instrument Preset

In most cases, it is recommended that the [PRESET] key/operation be recorded as the first keystroke recorded. This sets the instrument to its default state and avoids the risk of creating a program that depends on instrument settings that were present at the time of the keystroke recording but may be different when the program is run.

You can include the command to perform a preset in your program by pressing [PRESET] immediately after turning recording on. This inserts the following line prior to all other OUTPUT statements in your program:

```
OUTPUT @Rfna;'SYST:PRESET;WAI'
```

Specifically Select Parameters

If you do not want the instrument preset before a recorded program is run (for example, you may be recording a section of a larger measurement sequence), be sure to specifically activate every instrument setting that you will need in your automated sequence. For example, if you want the data format to be Log Mag, press [FORMAT] and then [Log Mag], even though Log Mag is already the default setting. This will generate a program line to specifically set the data format to Log Mag.

In some cases you may have to select another setting first and then re-select the original setting in order to generate the correct program line. For example, if you want to generate a program line to set the sweep trigger to Continuous, and you discover that it is already set to Continuous when you start recording, press [MENU] Trigger Hold first — then press [Continuous]. You can easily remove unwanted program lines generated by this procedure in the editor.

**Note**

Do not rely on the step keys or front panel knobs to set parameters. Use of step keys are not recommended because the results may depend on the function’s step size, which may change as other parameters change.
Use HP-IB Echo

HP-IB Echo is a useful analyzer feature that allows you to view the SCPI mnemonic or mnemonics corresponding to any operation executed from the front panel. To turn on HP-IB Echo, press \texttt{SYSTEM OPTIONS} HP-IB and \texttt{HP-IB Echo ON/off}. After doing this you will see a mnemonic appear in a dialogue box on the screen as you complete any key sequence that has a matching SCPI mnemonic.

This is the exact mnemonic that is generated in your recorded program during a recording session.

Using HP-IB Echo you can preview the SCPI mnemonic commands that will be stored in your program before you actually record them. While this is not essential, it can be very useful when you are in doubt as to what a particular key sequence will record, or precisely when a key sequence corresponding to a mnemonic is completed.
Running, Pausing and Stopping Programs

Program control — running, pausing and stopping an IBASIC program — can be managed from the analyzer front panel using various hardkeys and softkeys. These actions and their corresponding keys are described in this chapter.

A special case is an autostart program which runs automatically on power-up if it exists on the analyzer’s built-in floppy disk drive or RAM disk.

IBASIC programs may also be remotely controlled via SCPI commands over the HP-IB. For information on running, pausing and stopping programs from an external controller see Chapter 8, “Interfacing with External Devices.”

Starting Programs Automatically

When the analyzer is powered up, it automatically searches first the internal non-volatile RAM disk and then the built-in floppy disk drive for a program named AUTOST or AUTOST.BAS. When an AUTOST program is found, it is automatically loaded and executed.

The AUTOST program can be used for anything from configuring the analyzer for specific measurements, much like an internal instrument state Save/Recall register, to diagramming measurement setups using graphics commands, as in a guided measurement sequence.

Refer to Chapter 4, “Saving and Recalling Programs,” for information on using the analyzer to name programs before they are saved.

Running and Continuing a Program

To run an IBASIC program that is already in the analyzer program buffer, press the Run softkey in the [SYSTEM OPTIONS] IBASIC menu. The RUN command can also be executed from an external keyboard in either of two ways:

- Press the function key [F1] that corresponds to the Run softkey (see note below).

- Type RUN on a command line and press [Enter]. A command line is always available when an IBASIC display is partitioned. (See Chapter 5, “Developing Programs” for information about display partitions.) You can also activate a command line from an external keyboard with no IBASIC displays partitioned by pressing the [ESC] key on your external keyboard.
The prerun initialization phase consists of:

- Reserving memory space for variables specified in COM (both labeled and blank), DIM, REAL or INTEGER statements, or implied in the main program segment. Numeric variables are initialized to 0; string variables are initialized to the null string.

- Checking for syntax errors that require more than one program line to detect. Included in this are errors such as incorrect array references, and mismatched parameter or COM lines.

After prerun has been successfully completed, the program will begin the execution phase. Program lines will be executed until one of the following events occurs:

1. An END or STOP statement is encountered in the program.
2. The [RESET] hardkey is pressed to reset the instrument.
3. The [Pause] softkey is pressed to pause the program.
4. A PAUSE statement is encountered in the program.

Pausing a Program

When an IBASIC program is running on the analyzer a softkey menu is always available. This “Program Running” menu has seven user-defined softkeys and a Pause softkey. Press the Pause softkey to suspend execution of a program. Pause is the eighth softkey and is represented by [F8] on an external keyboard.

The program can also be paused by inserting a PAUSE statement in the program. The instrument responds as if you had pressed the Pause softkey. Refer to Chapter 5, “Developing Programs,” to learn how to insert statements in your recorded program. Note that PAUSE is one of the IBASIC keywords included in the editor’s label window (also described in Chapter 5).
To continue the program from a paused state, press the **Continue** softkey in the **SYSTEM OPTIONS** menu or **F2** on an external keyboard. This menu automatically appears when a program is paused. Continuing a paused program resumes program operation from where it was paused, retaining the current program context (variable values, etc).

Pausing a program does not close any files that have been opened by the program. You will not be able to perform any of the following disk operations after pausing a program that has left a file open on that medium:

- **RENAME FILE**
- **DELETE FILE**
- **DELETE ALL FILES**
- **COPY FILES**
- **COPY DISK**
- **FORMAT DISK**

To close all open files, you must complete the execution of the program or perform an IBASIC RESET. This can be done by pressing the [**P**RESET] hardkey. The [**P**RESET] hardkey is represented by **Ctrl** + **F4** on an external keyboard. Keystroke recorded programs do not open files and therefore avoid this problem.

### Stopping a Program

To stop a program completely, press the [**P**RESET] hardkey at any time while the program is running. This causes an IBASIC RESET. Placing a **STOP** statement in your program will also terminate the program, but does not perform an IBASIC RESET operation. The **END** statement can also be used to stop program execution, but it must be the last line in the main program segment.

The program remains in the program buffer after execution stops until it is cleared. To clear the program buffer, press [**SYSTEM OPTIONS**] [**IBASIC**] [**Utilities**] [**Clear Program**] or turn off the instrument.

For more information on the **PAUSE** and **STOP** statements see the “HP Instrument BASIC Language Reference” section of the *HP Instrument BASIC Users Handbook*, contained in this binder.
Saving and Recalling Programs

IBASIC programs can reside in memory, on disk, or in an external computer.

To transfer a program between the instrument’s buffer and a disk mass storage device, use the **SAVE RECALL** Programs menu. To access the **SAVE RECALL** Programs menu using an external keyboard, use **Ctrl** + **F1** (for **SAVE RECALL** ) and **F5** (for **Programs**).

The GET, SAVE, LOAD, STORE, RE-STORE, and RE-SAVE commands can be used within a program or from an IBASIC command line to transfer program files to and from mass storage. An autoload feature also exists to allow for a program (named AUTOST or AUTOST.BAS) to be automatically recalled from the internal non-volatile RAM disk or the built-in floppy disk and run at power-up.

Another mode of program transfer is between the analyzer and an external controller, such as an HP Series 200/300/700 controller. Using an external controller, you can combine the convenience of keystroke recording in IBASIC with the ease of program editing in a dedicated external workstation by recording the measurement sequence and then uploading the program to the external controller for further editing. Fully developed programs may be downloaded from an external controller as well. The methods of transferring programs between the analyzer and an external controller are described in detail in Chapter 8, “Interfacing with External Devices.”

This chapter describes all program transfer operations between the program buffer and the analyzer internal non-volatile RAM disk, internal volatile RAM disk, internal floppy disk drive and external mass storage devices (disk drives).

---

**Note**

The IBASIC file system can work with both LIF (Logical Interchange Format) and DOS (Disk Operating System) formatted disks. When it catalogs or loads files from a disk, the analyzer automatically recognizes the correct disk format.
Selecting a Disk

When the **SAVE RECALL Programs** menu is selected the analyzer automatically catalogs the selected disk or memory. The selected disk is one of the following mass storage devices:

- Internal Non-Volatile RAM Disk
- Internal Volatile RAM Disk
- Internal Floppy Disk Drive
- External Disk Drive

To select a mass storage device press the **Select Disk** softkey in the **SAVE RECALL** menu. Then press the key corresponding to your choice. The HP-IB address of the external disk drive is set under the **SAVE RECALL Select Disk Configure Ext. Disk** menu.

Saving a Program

To save the current contents of the analyzer program buffer to a file, press **Save Program** in the **SAVE RECALL Programs** menu. If desired, specify the type of file, binary or ASCII, with the **File Type** softkey; default is ASCII. The program is saved to an ASCII file with a default name on the currently selected mass storage device or disk. Each time the **Save Program** key is used a new file is created. These files are named **PROG0.BAS**, **PROG1.BAS**, ... with the number being changed for each new file. For portability, save files in ASCII.

![Figure 4-1. The SAVE RECALL Screen](image_url)
If you are re-saving a program — that is, saving a file to a disk that already contains the file name — press [SAVE RECALL] Programs and use the arrow keys to highlight the name of the file to be re-saved. Then press Re-Save Program and the file is saved. The disk is automatically catalogued when the [SAVE RECALL] menu is selected.

The Re-Save Program softkey can also be used to save a new program with a non-default file name. Press Re-Save Program. Enter the new program’s name using the external keyboard or the internal label maker. If no file with that name exists on the disk a new file is created.

---

**AUTOST Program**

IBASIC allows you to designate a program to be automatically loaded and run when the instrument is first powered up. To make an autoloading program save it with the file name AUTOST on the internal floppy disk drive or internal non-volatile RAM disk. This can be done from the [SAVE RECALL] Programs menu by pressing Save AUTOST or by using the Re-Save Program softkey and entering the file name AUTOST.

When the analyzer is powered up, it automatically searches first the internal non-volatile RAM disk and then the built-in floppy disk drive for a program named AUTOST or AUTOST.BAS. When an AUTOST program is found, it is automatically loaded and executed.

---

**Recalling a Program**

To recall a program file from mass storage to the program buffer, use the [SAVE RECALL] Programs menu to catalog the disk. Select the desired mass storage device or disk, use the arrow keys to highlight the file and press Recall Program.

The recalled program file is entered into the program buffer one line at a time and checked for syntax errors. Lines with syntax errors are commented out and the IBASIC syntax error is displayed briefly in an error message and written to the CRT at the same time. To view error messages logged to the CRT, use the [SYSTEM OPTIONS] IBASIC IBASIC Display menu to allocate a screen partition for IBASIC.

---

**Note**

Any program recalled to the program buffer using the [SAVE RECALL] Programs menu will overwrite the current contents of the program buffer. Be sure to save your current program before recalling another program from disk.
Developing Programs

For many applications, you can use keystroke recording to create and run programs without needing to alter the program code that is generated. However, with some knowledge of the IBASIC language and the program development capabilities of the analyzer, you can significantly increase the power of your recorded programs or create your own programs from the ground up.

This chapter describes the operation of the following keys in the SYSTEM OPTIONS IBASIC menu, and any softkeys found in their underlying menus:

- **Edit**
- **IBASIC Display**
- **Utilities**

**Edit** places you in the editor where you can make changes to your program on a line-by-line basis.

**IBASIC Display** menu allows you to select what part, if any, of the CRT display is available for the use of IBASIC. An IBASIC display partition provides you with a command line you can use to execute IBASIC commands from an external keyboard. It also provides an area for viewing graphics and program output.

**Utilities** allows you to Clear Programs from the program buffer, allocate memory for program use, or secure program lines.
External Editors

In addition to using the built-in IBASIC editor, programs can be developed in the following external environments.

- HP BASIC editors
- ASCII word processors

The external editing environments provide many advantages, the most notable being speed and flexibility. Precautions must be taken when using ASCII word processors because they do not provide the syntax checking available when using the internal editor.

After editing a program in an external environment, the best practice is to GET the program from an IBASIC command line using the following procedure (instead of using the SAVE RECALL keys described in Chapter 4).

1. Partition an IBASIC display (as described later in this chapter).
2. Use an external keyboard to enter the command GET "PROGO: ,4" (this command loads a program file PROGO from the internal floppy disk drive).
3. Watch the IBASIC display as the program is loaded — syntax errors result in error messages displayed on the screen.
4. Edit the program to correct any errors found.

HP BASIC

The HP BASIC editor checks for the syntax of the version of HP BASIC being used. Because IBASIC is a subset of HP BASIC it may not find all of the errors — the most common error is the use of HP BASIC commands that are not supported by IBASIC. For a listing of the commands supported by IBASIC refer to Chapter 10, “IBASIC Keyword Summary”.

ASCII Word Processors

When an ASCII word processor is used to edit a program no syntax checking occurs until the program is loaded by the instrument. Another complication with using a word processor is that program line numbers are not automatically renumbered when new lines are inserted.

It is recommended that you renumber the program, as described later in this chapter, to reduce the possibility of errors. Errors in numbering lines usually do not result in a syntax error, they write over other program lines.
Editing Your Program Using **Edit**

The built-in editor may be used for creating and altering lines in an IBASIC program. Those familiar with the editor found in HP BASIC will find it somewhat similar to the instrument’s IBASIC editor; others should find it easy to learn and use. This section tells you how to edit and enter an IBASIC program.

To start the editor, press the **Edit** softkey in the **SYSTEM OPTIONS IBASIC** menu or **F4** on an external keyboard. You will see the program appear on the display with a cursor on the first line of the program, as shown in Figure 5-1. If the program buffer is empty, the first line number 10 appears with the cursor positioned to begin entering text.

```
CALL PRINT ASRT SUB SUBEND DATA LOCAL DIM BIT ABCDEFGHIJKLMNOP
10 |==========================================================================| Edit
20 ! This program measures the transmission and                           Insert
30 ! reflection characteristics of a bandpass filter                     Line
40 |==========================================================================|
50 ASSIGN #h8711 TO 800                                              Insert
60 ON KEY 0 LABEL 'TRAN' CALL Transmission                             Char
70 ON KEY 1 LABEL 'REFL' CALL Reflection                                Delete
80 ON KEY 3 LABEL 'SETUP' CALL Setup_diag                               Line
90 ON KEY 5 LABEL 'EXIT' GOTO End_prog                                 Recall
100 LOOP                                                                Line
110 DISP 'WAITING FOR SELECTION'                                       Delete
120 END LOOP                                                           Char
130 End_prog:DISP                                                       Edit
140 END                                                                Char
150 |==========================================================================|
160 SUB Transmission                                                   Prior Menu
170 Transmission: 1                                                     
180 OUTPUT @#h8711: "CONF 'FILT:TRAN'")

200 OUTPUT @#h8711: "SENS1:FREQ:CENT 175 MHZ"                        
```

**Figure 5-1. The HP IBASIC Program Editor**

The analyzer editor is accompanied by a “Label Window” at the top of the screen. This window is filled with characters and IBASIC keyword commands and has its own cursor.

The current program line (the line containing the cursor) always appears as two lines on the screen, allowing you to enter up to 108 characters if needed. All other lines have only their first 51 characters displayed (excluding line numbers).

Each line has a numeric field in the first 6 columns in which program line numbers are right justified. Although program lines are automatically numbered by the editor, you can edit the current line number to copy or move it to a different location in the program. The range of line numbers is from 1 to 32767. To end an editing session press the **Prior Menu** softkey in the edit menu or **F6** on an external keyboard. This will return you to the **SYSTEM OPTIONS IBASIC** menu.
The IBASIC Editor Softkeys

The editor has two sets of softkey menus, the Edit keys and the Character Entry keys. The edit menu is activated when you press SYSTEM OPTIONS IBASIC Edit. The menu box above the softkeys shows the label Edit.

The edit menu provides the following softkeys:

- Insert Line (F1)
- Insert Char (F2)
- Delete Line (F3)
- Recall Line (F4)
- Delete Char (F5)
- Enter (F6)
- Prior Menu (F8)

The character entry menu is described in the “Editing from the Front Panel” section of this chapter.

Recording into an Existing Program

One way to enter lines into your program is to use the keystroke recording capabilities of IBASIC. To record measurement sequences or other front panel operations into your program follow the procedure described below.

1. Activate the editor by pressing SYSTEM OPTIONS IBASIC Edit.

2. Use the step keys on the analyzer or the cursor keypad on an external keyboard to position the cursor on the line above which you want the recorded statements inserted.

3. Press Prior Menu to exit the editor.

4. Press Key Record On Off to activate keystroke recording.

5. Record the measurement sequence or front panel operation.

6. Press SYSTEM OPTIONS IBASIC Key Record on Off to conclude the recording session.

The inserted recording acts the same as if you had pressed Insert Line in the editor, and generated OUTPUT statements in insert mode.

Note

The ASSIGN 0Hp8711 to 800 statement is NOT generated when you are recording into an existing program and MUST be included in your program prior to any recorded OUTPUT commands. If you initially created the program using recording, this statement should already exist. If it does not exist, you will need to enter it.
Editing with an External Keyboard

With an external keyboard connected to the analyzer, it is easy to edit or create an IBASIC program using the internal editor. Note that the Front Panel Editor described in the next section is always available, even when an external keyboard is in use.

Note

The analyzer and the IBASIC editor work with IBM PC-AT compatible keyboards (US only) that have a standard DIN interface. Non-US language keyboards will not cause an error, they simply will not be recognized as different from the US keyboard. A compatible keyboard can be purchased by ordering option 1CL with the analyzer. Keyboards with a mini-DIN connector will need a mini-DIN to DIN adapter, HP part number C1405-60015.

The PC-AT keyboard, Figure 5-2, has four major key areas: the typewriter keypad, the numeric keypad, the cursor keypad, and the function keys. Alphanumeric text can be entered using the typewriter and numeric keypads as needed. The cursor keypad can be used to move the cursor up/down a line or left/right to the next character positions. The function keys of the keyboard map to the softkeys on the analyzer front panel.

![Keyboard Diagram](image)

**Figure 5-2. The PC Keyboard**

Connect the keyboard to the rear panel DIN connector of the analyzer with the power off. Turn on the power and load the IBASIC program to be edited. Select the **System Options** menu and use the cursor keypad to position the cursor within the program for editing operations. The Page Up and Page Down keys on the keyboard scroll through the program quickly and easily.
Inserting Lines

Insert one or more program lines above an existing line by placing the cursor on that line and pressing Shift + Insert on the keyboard. This key combination functions as a toggle to turn insert mode on and off.

As an example, assume you want to insert some lines between two adjacent program lines numbered 90 and 100. Place line 100 in the current line position and press Shift + Insert. The program display "opens" and a new line, number 91, appears between line 90 and line 100. Enter the inserted line and another inserted line, number 92, will appear. If, after continuing to enter lines in this manner, the inserted line number increments to 100, then the current line 100 will be renumbered one higher to accommodate the inserted line.

To stop inserting lines either press Shift + Insert again or use the cursor keys to move to another program line. Make sure you have entered any changes to your final inserted line (with the Enter key) before exiting the insert mode. Remember any changes you have made to the current line will be lost if you move the cursor to another line without pressing Enter.

Editing Lines

Use the cursor keypad on the keyboard to move around the program for editing. The left and right arrow keys move within a program line while the up and down arrow keys move between lines. The alphanumeric keypad on the keyboard can be used for entering or editing text. Another key that is useful is the Delete key, which deletes the character highlighted by the cursor.

When you finish editing or changing a program line, store it into the program by pressing Enter on the keyboard. The computer checks the line for syntax errors and converts letter case to the required form for names and keywords (IBASIC commands). If no errors are detected, it then stores the line in the program buffer.

Entering Program Lines

When you finish entering or changing a program line, to store it into the program buffer you must ENTER it in one of four ways:

1. Use the Enter key on the front panel of the analyzer.
2. Use the Enter softkey on the instrument.
3. Use the Enter or Return key on the external keyboard.
4. Use the function key on the keyboard (F6) that represents the analyzer's Enter softkey.

The computer checks the line for syntax errors and converts letter case to the required form for names and keywords (IBASIC commands).

If no errors are detected, it then stores the line.

Note: If you edit or enter text on the current program line and then move off the line without pressing ENTER, all editing on the line will be lost.

5-6 Developing Programs
Editing from the Front Panel

Use the step keys to move the cursor up and down the lines in the program. When the cursor is located at the beginning of a line you want to change, use the knob to position the cursor within the line.

Character Entry

The character entry menu and the associated label window are activated by pressing the Insert Line or Insert Char softkeys. The knob and step keys now move the cursor in the label window.

Use the knob or step keys to move the label window’s cursor until it highlights the desired letter or keyword and press Select Char/Word. Continue editing until the line is correct. Press Enter. The computer checks the line for syntax and then stores it in the program if the syntax is correct. Press Prior Menu to return to the edit menu.

The character entry menu provides the following softkeys:

- **Select Char/Word** (F1) inserts the character or word highlighted by the label window cursor at the position marked by the program cursor.
- **Space** (F2) inserts a space at the position marked by the program cursor.
- **Delete Char** (F3) deletes the character highlighted by the program cursor.
- **Backspace** (F4) deletes the last character before the program cursor.
- **Enter** (F5) enters the edited program line.
- **Prior Menu** (F8) returns to the edit menu and de-activates the label window.

The Label Window

The label window is a scrolling list of the most common characters, symbols and keywords used in IBASIC programming. It contains the uppercase alphabet, the numbers 0 to 9, symbols such as single and double quotation marks, parentheses, signs for mathematical and string operations as well as numerous other characters and symbols.

It also contains the following IBASIC keywords:

- **ABORT**
- **ASSIGN**
- **BIT**
- **CALL**
- **CLEAR**
- **DATA**
- **DIN**
- **DISP**
- **END**
- **ENTER**
- **FOR**
- **GOTO**
- **IF**
- **INPUT**
- **INTEGER**
- **LIST**
- **LOCAL**
- **NEXT**
- **NOT**
- **OUTPUT**
- **PAUSE**
- **PRINT**
- **SUB**
- **SUBEND**
- **THEN**
- **TO**
- **WAIT**
Inserting Lines
To insert one or more program lines above any existing line, place the cursor on the existing line and press Insert Line. This causes the cursor to move to a new line that appears above the existing one. Enter and store the inserted line and another inserted line will appear. Remember, each line must be ENTERed or any changes will be lost when the cursor is moved to a different line.

Removing Program Text
You can remove individual characters or entire lines from within the editor.

Deleting Characters
The Delete Char softkey removes the character under the cursor and moves all characters to the left one place. Repeatedly pressing Delete Char will cause text to the right of the cursor to be removed one character at a time. The Delete Char softkey functions the same in both the line number and program statement fields. When used in the line number field, it deletes only line numbers to the right of the cursor (not program statement characters).

When using an external keyboard there are other keys that perform the same function as the Delete Char softkey. These are the Delete key in the cursor keypad and the function key that maps to the appropriate softkey, F5 for the edit menu or F3 for the character entry menu.

Another way to remove text on a line is by backspacing. Pressing the ←/→ hardkey or the Backspace softkey on the front panel of the analyzer removes the letter to the left of the cursor and moves the cursor (and all characters to the right of the cursor) one space to the left. The F4 function key or the Backspace key on the typewriter keypad of the external keyboard perform the same function. When the cursor is on a line number, using backspace simply moves the cursor back one position without deleting the number.

Deleting Lines
The Delete Line softkey allows you to remove the current program line. When the current program line disappears, all subsequent lines in the display move up one line, but are not renumbered. The cursor maintains its column-relative position on the next highest numbered line.

If Delete Line is pressed when the cursor is on the last program line, the line text is removed but the line number remains with the cursor resting in the first column of line. This puts the editor in insert mode on the last line of the program (see "Inserting Lines"). (To get out of insert mode, simply move the cursor up one line.)

Pressing Delete Line will NOT remove a subprogram line with the SUB keyword in it unless all program lines belonging to that subprogram have already been deleted. A block of program lines can be deleted by executing the command DELETE x,y from an IBASIC command line (where x is the first line number in the block and y is the last line number).

When using an external keyboard there are other keys that perform the same function as the Delete Line softkey. These are Shift + Delete in the cursor keypad and the function key (F3) that maps to the Delete Line softkey in the edit menu.

5-8 Developing Programs
Recalling a Deleted Line

The last line that was deleted using Delete Line is buffered in the analyzer. To recall this line press the Recall Line softkey or F4 on an external keyboard. Press Enter to restore the line to the program.

Renumbering, Copying, Moving, and Indenting Lines

If you want to change the line number of an edited program line, simply move the cursor to the line number field and enter the line number you want. Changing the line number causes a copy operation, not a move. Therefore, if you only want to move the line, change the line number first, press Enter and then delete the original line. If you want to create an edited copy of the current line, edit the line and then change the line number and press Enter. The edits will only appear in the copied line.

If you are inserting a program line and you change the line number, the line will move to its new location when you ENTER it. The editor will remain in insert mode at the new location in the program.

You will notice that when the cursor is in the line number field, entries operate in an overtype fashion rather than in the insert fashion as in the text portion of the program line. Also the (backspace) key simply moves the cursor over line numbers without deleting the number.

Note

To renumber the entire program, IBASIC supports the RENumber command BUT you need an external keyboard to execute it. The command can be executed by following the steps listed below.

1. EXIT the edit mode by pressing Prior Menu until the SYSTEM OPTIONS IBASIC menu is active.

2. Partition an IBASIC display as described next in this chapter.

3. Enter the command REN x,y (where x is the new beginning line number and y is the increment) from the command line of the IBASIC display.

4. Another way to “renumber” program lines with an external keyboard is to use the COPYLINES and MOVELINES commands. Use the INDENT command to make your code more readable.
Using **IBASIC Display**

Pressing the **SYSTEM OPTIONS** **IBASIC Display** softkey (F7) on an external keyboard allows you to allocate a partition of the analyzer's display to be used by your program or, alternately, to return any allocated partition to the analyzer.

The analyzer display is divided into two small partition areas (Upper and Lower) or one large area (Full), which encompasses both the Upper and Lower partition areas.

All screen output commands, such as PRINT and DRAW, require that you allocate a partition of the screen in order to view the results of the command. This can be performed in your program or interactively using the **IBASIC Display** softkey. Allocating display partitions can be accomplished from within your program using the SCPI mnemonic "DISP:PROG" and specifying the parameter UPPER, LOWER or FULL. For example the statement

```
OUTPUT 600;"DISP:PROG FULL"
```

allocates the entire display, corresponding to selecting **Full** from the **IBASIC Display** menu.

An IBASIC display partition cannot occupy the same location as a measurement channel display. When an IBASIC display is partitioned it limits the amount of the CRT available to simultaneously show measurement data. Table 5-1 shows the **IBASIC Display** menu softkeys, their corresponding SCPI mnemonics, their functions and the measurement data that can be viewed when the display partition is allocated.

</tbody>
</table>

5-10 Developing Programs
Note

When the UPPER or LOWER display partition is selected, the measurement display automatically selects the “split-screen” format. This format uses half of the CRT to display each channel’s measurement data. Channel 1 data is always shown on the upper half of the screen, channel 2 data is shown on the lower half. The split-screen format allows measurement data to be viewed simultaneously with IBASIC program output. For more information about the split-screen format, or other parts of the measurement display, refer to the analyzer User’s Guide.

Most display allocation should be handled by your program via the SCPI mnemonics. These softkeys are best utilized during program development.

An IBASIC partition can be very useful during program development. It can be used to view program output, to query variables and to execute IBASIC commands (such as GET and REN) outside of your program. Figure 5-3 shows the relative size and location of the different IBASIC partitions and their command and display lines.

![IBASIC display partitions diagram]

Figure 5-3. The IBASIC display partitions

More information about using display partitions within a program is available in Chapter 7, “Graphics and Display Techniques.”
Using Utilities

Pressing the **System Options** IBASIC Utilities softkey (F6 on an external keyboard) allows you to clear the program buffer, allocate memory for program use, or secure your program.

- Clear Program (F1)
- Memory Size (F2)
- Secure (F3)

Executing the **Clear Program** erases the current program buffer and frees all memory currently allocated. Memory size (see below) is reset to 8192 bytes. You will be prompted to ensure you do not accidentally erase the program.

**Memory Size** allows you to set stack memory to be used by your program. At power up it is set by default to 8192 bytes. However, when a program is (RUN), the analyzer will try to automatically set the Memory Size large enough to accommodate the program’s Stack and COM memory requirements.

For some programs the automatic memory sizing will be too small and you will get the message:

**Error 2 in 100 Memory overflow**

When this error occurs, you must manually set the **Memory Size** to the value in bytes required by your program, up to the available memory in your system.

**Secure** is used to secure lines of your program. Secured lines cannot be listed, edited, or displayed. After you press this key you will see:

- Start Line # (softkey 1)
- End Line # (softkey 2)
- Perform Secure (softkey 4)

After you have set the start and stop line numbers, execute the **Perform Secure** operation.

**Caution** Once you have secured your program lines, there is no way to remove the security. Therefore, do not secure the only copy of your program. Make a copy of your original program, **Secure** the copy, and keep the original in a safe place. This prevents unauthorized users from listing your program.
Debugging Programs

The process of creating programs usually involves correcting errors. You can minimize these errors by using keystroke recording for measurements and other front panel sequences and by writing structured, well-designed programs.

Of course bugs can and do appear in even the best designed programs and IBASIC contains some features that can help you to track them down. Some IBASIC capabilities useful for program debugging are simple and, used properly, can be very helpful. Some of these capabilities are:

- **RUN** or **CONTINUE** your program
- **STEP** through your program, executing one line at a time
- Display the last error encountered in your program
- Examine program variables

By examining the values assigned to variables at various places in the program, you can get a much better idea of what is really happening in your program.

By inserting a **PAUSE** statement in your program you can pause the program at any line and then examine the values of variables at that point in the program. You can then press **Continue** in the **SYSTEM OPTIONS** IBASIC menu to resume operation to the next **PAUSE** statement (or the program end).

These capabilities can be used together to effectively examine the program's operation and solve your particular problems.

**Note**

Most of the debugging techniques described in this chapter make use of an external keyboard. The analyzer and the IBASIC editor work with PC-AT compatible keyboards (US only) that have a standard DIN interface. Non-US language keyboards will not cause an error, they simply will not be recognized as different from the US keyboard. A keyboard can be ordered with the analyzer by ordering option 1CL.
Setting Breakpoints

A common method of debugging a program involves the use of breakpoints. A breakpoint causes the program to stop before executing a specified line so that you can examine the program state at that point. In IBASIC this can be accomplished by inserting PAUSE statements in the program code. Note that PAUSE is one of the IBASIC keywords included in the editor's label window (described in Chapter 5, "Developing Programs"). When the program is then run, you can use the command line to check or change variable values.

Execution of the program can be resumed in one of two ways.

- Press **Stop** ([F3] on an external keyboard) to execute next program line.
- Press **Continue** ([F2] on an external keyboard) to continue the program until the next PAUSE, STOP or END statement is encountered.

Examining Variables

To examine a variable it is necessary to pause the program. Pausing the program can be accomplished by pressing the **Pause** softkey ([F8] on an external keyboard) that is available when a program is running, or by inserting a PAUSE statement in your program.

A command line becomes active when an IBASIC program is paused or stopped and an IBASIC display partition is present. (For information on creating an IBASIC display partition, see “Using IBASIC Display” in Chapter 5, “Developing Programs.”) You may also activate the command line when no IBASIC window is partitioned by pressing the [ESC] key on the external keyboard. A cursor will appear in the lower left portion of the screen when the command line is active. Strike the [ESC] key again to de-activate. Once the command line is active, a variable can be examined in two ways. Both methods require the use of an external keyboard.

1. Enter the variable name (without a line number) on the command line. This results in the value assigned to that variable being shown in the display line of the IBASIC window.

2. Execute the command **PRINT Value** from the command line (where Value is the name of the variable being examined). This results in the value assigned to that variable being shown on the print screen of the IBASIC window.

To examine a variable without accessing a command line it is necessary to add the statement **PRINT Value** (or **DISP Value**) to the program before the **PAUSE** statement that temporarily stops the program. **PAUSE**, **PRINT** and **DISP** are all keywords that are included in the IBASIC editor’s label window (see Chapter 5, “Developing Programs” for a description of the label window).
Note  An IBASIC display partition must be active to view the results of a PRINT statement or to access a command line. The display line (accessed with the DISP command) is available even when no IBASIC display is present.

Examining Strings
Enter string variables as you would any other variable. Any string variable entered without delimiters will display as much of the string as will fit on the display line of the screen (up to 58 characters).

To select only a section of a string, use the IBASIC substring syntax (see the "HP Instrument BASIC Programming Techniques" section of the HP Instrument BASIC Users Handbook). For example, to examine the 7 character substring starting at the second character of A$ enter A$[2;7] on the command line or execute the command PRINT A$[2;7].

Examining Arrays
To select an array to be examined you can either select individual elements or the entire array. For example the entry:

    I_array(1), I_array(2), I_array(3)

selects the elements 1 through 3 of the array I_array to be displayed.

You may select an entire array to be examined by entering the array variable name and specifying a wildcard (*) for the element (such as I_array(*)). If I_array(20) is an integer array, and the first and second elements are set to 100, entering I_array(*) would display:

    100 100 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Individual array elements (e.g., I_array(17)) can also be specified in the same way as any other single variable.
Displaying the Last Error Encountered

It is sometimes useful to review the last error encountered by a program that is being run. This is done from the command line by examining the value assigned to the variable name ERRM$. This value will include the error number and message of the last error encountered by the program.

An additional method of displaying the error message is to use an error trapping subroutine.

For example, insert the following line at the beginning of a program.

```
ON ERROR GOSUB Errormsg
```

The subroutine Errormsg should then be included at the end of the program (after execution is stopped but before the END command).

```
100 Errormsg: !
110 DISP ERRM$
120 PAUSE
130 RETURN
```

The error message is automatically shown on the display line of the IBASIC window and program execution is paused when an error message is encountered.

You may also encounter SCPI errors, in addition to IBASIC errors. SCPI errors can occur when using the OUTPUT command to control the analyzer, when a command syntax is unrecognized or incorrect. For more details on SCPI errors, refer to the *Programmer's Guide*. 

---

6-4 Debugging Programs
Graphics and Display Techniques

The analyzer has two measurement channels which can be displayed simultaneously. The instrument’s screen can be split into two trace areas for this purpose (upper for channel 1 and lower for channel 2). Additionally, the two measurements can be overlaid onto one full size screen (the default setting). For more information, refer to “Automating Measurements” in the User’s Guide.

IBASIC programs have the ability to allocate portions of the instrument’s display for program output, including text and graphics. This section provides a description of the various programming techniques used to do both. Any of the three measurement display areas, called display partitions, can be used by an IBASIC program. These partitions are shown in Figure 7-1.

![Figure 7-1. Display partitions on the analyzer]

Using the Display Partitions

Many IBASIC commands (such as PRINT, DISP, CLEAR SCREEN, MOVE, DRAW and GCLEAR) require a display as an output device. These commands output data to the screen by writing to a screen buffer. Since IBASIC programs share all the hardware resources with the instrument, the display must be shared for instrument and program use.
In order to view this output buffer, a portion of the display must be released from the instrument. When no program is running, you can do this manually, using the **SYSTEM OPTIONS** IBASIC IBASIC Display softkey menu. To do this within a running program requires sending a command to the analyzer both to borrow a part of the display and again to return it for the instrument’s use.

This process is called the allocation of display partitions. Manual allocation of display partitions is described in Chapter 5, “Developing Programs.” Table 7-1 below includes a summary of the available partitions, their locations and the SCPI mnemonic used to select each partition.

<table>
<thead>
<tr>
<th>SOFTKEY</th>
<th>SCPI MNEMONIC</th>
<th>ALLOCATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Home</td>
<td>DISPlay:PROGram OFF</td>
<td>No Display</td>
</tr>
<tr>
<td>Full</td>
<td>DISPlay:PROGram FULL</td>
<td>The Whole Display</td>
</tr>
<tr>
<td>Upper</td>
<td>DISPlay:PROGram UPPer</td>
<td>Upper Channel Area</td>
</tr>
<tr>
<td>Lower</td>
<td>DISPlay:PROGram LOWer</td>
<td>Lower Channel Area</td>
</tr>
</tbody>
</table>

**Allocating Display Partitions**

To request a display partition from the analyzer for use by an IBASIC program, send the instrument the corresponding SCPI mnemonic. "DISP:PROG UPPer" allocates the upper partition, "DISP:PROG LOWer" allocates the lower partition, and "DISP:PROG FULL" allocates the full screen partition.

For example, to print a message to the upper partition area, you might use a program segment like this:

30 ASSIGN @Hp8711 TO 800  
40 OUTPUT @Hp8711;"DISP:PROG UPPer"  
50 CLEAR SCREEN  
60 PRINT "This is the upper partition"

To be sure that you are not writing to a partition that has not yet been assigned, you should include a **WAIT** statement or, even better, add a SCPI query command followed by an **ENTER** statement to synchronize the program with the instrument. The previous example might then look like this:

30 ASSIGN @Hp8711 TO 800  
40 OUTPUT @Hp8711;"DISP:PROG UPPer"  
42 OUTPUT @Hp8711;"DISP:PROG?"  
44 ENTER @Hp8711;Screen$  
46 IF Screen$<>"UPP" THEN GOTO 42  
50 CLEAR SCREEN  
60 PRINT "This is the upper partition"

The mnemonic **DISP:PROG?** (line 42 above) requests the instrument to send the current partition status. The **ENTER** statement on the next line reads that status and then continues.

7-2 Graphics and Display Techniques
De-Allocating Display Partitions

To return the display partition to the analyzer for use as a measurement screen, use the "DSP:PROG OFF" mnemonic. This should be done before the termination of any program that has allocated a display partition. It may also be required within the program to allow the user to view instrument measurement data. The following example demonstrates this command:

830 OUTPUT @HP8711;"DSP:PROG OFF"

Operation with No Display Partition

IBASIC programs can also access the analyzer’s display when no partition has been allocated. This can be done through the use of certain areas of the screen. One of these areas is to the right of the measurement display. This area is reserved for softkey labels. It can be accessed using the ON KEY statement.

A second area is a display line (or command line) that appears when no part of the display is allocated for use by IBASIC. This display line, which is located at the lower left corner of the active channel graticule, appears when needed by the INPUT or DISP commands or when activated. To activate the command line, press [ESC] on an external keyboard. Figure 7-2 shows an example of the use of this display line. When the INPUT command is being used, the IBASIC editor’s label window and character entry softkey menu appear. Refer to Chapter 5, “Developing Programs,” for a description of the IBASIC editor.

![Figure 7-2. Using INPUT with no display partition](image-url)
In addition to the commands described above, the analyzer has “User Graphics” commands that can write to any of the display partitions. These commands can be used to write to measurement windows as well as the IBASIC window. These commands are described in the “SCPI Graphics Commands” section of this chapter.

Displaying Text

Most of IBASIC’s text capabilities are covered in detail in the “HP Instrument BASIC Programming Techniques” section of the *HP Instrument BASIC Users Handbook*. The PRINT statement works the same way in every display partition. Information is printed starting at the top left corner of the current partition and continues until the display line of the partition is reached. The screen then scrolls up to allow additional lines to be printed. Figure 7-3 shows the different display partitions and the location of text printed to them. Note that causing the screen to scroll does not affect any graphics displayed on the screen, since text and graphics are written to different planes of the display.

All partitions have a width of 58 characters. The height varies according to partition. Both upper and lower partitions contain 10 lines, while the full partition contains 22 lines.

This information is useful if you are using the PRINT TABXY statement to position text. For example, the following program segment prints a message in the center of the full partition (assuming it has been allocated earlier in the program).

```
100 Maxlines=22
110 Tabx=(58-LEN("This is CENTERED text."))/2
120 PRINT TABXY(Tabx,Maxlines/2);"This is CENTERED text."
```

![Figure 7-3. Printing to a display partition](image)

7-4 Graphics and Display Techniques
A useful technique to get text onto the screen quickly is to write your display message to a long string using the OUTPUT statement, and then print the string to the screen. For large amounts of text, this speeds up screen display time considerably. The following program segment demonstrates this:

```
60 DIM Temp$[100],Big$[2000]
70 OUTPUT Temp$;"This is the first line of text"
80 Big$=Big$&Temp$
90 OUTPUT Temp$;"This is the second line of text"
100 Big$=Big$&Temp$
110 PRINTER IS CRT; WIDTH 2000
120 PRINT Big$
```

The OUTPUT statements in this example are used to copy each line of the message into the variable Temp$ and append a carriage return.

You can also print to the screen using the OUTPUT statement in conjunction with the display address (1). For example, line 150 below writes a string to the screen.

```
150 OUTPUT CRT;"OUTPUT 1 WORKS WELL TOO"
```

**Pop-up Message Windows and Custom Annotations**

From your IBASIC program, you can replace instrument annotations with user-defined annotations. You can change the X-axis labels and channel annotations to customize the display. Pop-up messages may also be used to display permanent or temporary messages. Refer to “Automating Measurements” in the User’s Guide.

**Graphics Initialization and Scaling**

In all partitions, display coordinate 0,0 is at the bottom left corner and clipping occurs automatically if the X,Y coordinate exceeds the displayable range of the current partition. Figure 7-4 shows the different partitions and the pixel dimensions (GESCAPE values) for each.

After a GINIT command, the display is dimensioned as 100 GDU’s (Graphical Display Units) high and 245 GDU’s wide (assuming full partition). This gives a RATIO result of 2.45 and provides the same results as issuing a WINDOW 0,245,0,100 command. In order to prevent circles from appearing oval shape, this ratio should be maintained. You can also issue a WINDOW 0,861,0,351 command. This will maintain the same ratio but the display will now be dimensioned in actual pixel unit. This may be more useful than the default GINIT values since fractional display units are not needed, allowing integers only to be used; thus speeding execution. These are also the same values that are returned by utilizing the GESCAPE command (see BARCODE program example). The GESCAPE command will always set the current pixel dimension sizes. Because the results of this command can vary drastically with partition size, you must first partition the display BEFORE executing the GINIT and GESCAPE commands.

**Note**

Upon power up, the default display coordinates are 0,861,0,351 and will remain that until a GINIT is performed. It is recommended that a GINIT command always be part of any graphics program and that it be executed only after the display partition is set.
Using Graphics

IBASIC’s graphics commands are easy to understand and use. You can use the MOVE statement to move the “pen” to a specific pixel location (without drawing) and then draw a line from the current pen location to another pixel coordinate using the DRAW statement. The GCLEAR statement removes all graphics.

The PEN command provides an easy method of erasing lines drawn by the DRAW command. When PEN 1 is issued (the default state), all DRAW commands act normally, drawing a line with the full intensity. When PEN 0 is issued, all DRAW commands erase any pixels their path encounters. Where there are no lines in the path, no change is visible. As an example of using the MOVE and DRAW commands, the following statement moves the logical pen to a point 100 units to the right of, and 150 units above, the lower left corner of the display:

```
100  MOVE 100, 150
```

This statement then draws a line to coordinates (200,10):

```
110  DRAW 200, 10
```

Finally, these two statements erase the previously drawn line:

```
120  PEN 0
130  DRAW 100, 150
```

Although text and graphics appear together, you can clear them separately. Use CLEAR SCREEN to clear the text. Use GCLEAR to clear the graphics.
Drawing Figures

Some IBASIC keywords listed below may be used to simplify drawings and setup diagrams. See also, the paragraph below titled “Graphics Exceptions”.

POLYGON - Draws all or part of a regular polygon

RECTANGLE - Draws a rectangle

LABEL - Produces alphanumeric labels

CSIZE - Sets size and aspect ratio of labels

LDIR - Defines the angle at which a label is to be drawn

LORG - Defines the relative origin of a label

These keywords are used in the “BARCODE” program example listed in Chapter 11, “Example Programs”, and on the IBASIC Example Programs Disk. The keywords appear in the subprograms ‘Box’, ‘Circle’, and ‘Label’ described below.

1620    ! Draw a box in the active IBASIC partition
1621    ! Xpos,Ypos specify the CENTER of the box
1622    ! Xsize,Ysize are width and height dimensions
1623    ! Sc is a scaling factor for the figure being drawn
1624    ! 1.79 is a correction factor used by the 8711 only
1630    Box:SUB Box(Xpos,Ypos,Xsize,Ysize)
1640    COM /Scale/ Sc,INTEGER X,Y
1650    MOVE X+(Xpos-Xsize/2)*Sc,Y+(Ypos-Ysize/2)*Sc
1660    RECTANGLE Xsize*Sc,Ysize*Sc*1.79 !8711 Pixel H:W Ratio
1670    SUBEND

1680    ! Draw a circle in the active IBASIC partition
1682    ! Xpos,Ypos specify the center of the circle
1683    ! Radius is the size of the circle
1684    ! Sc is a scaling factor for the figure being drawn
1690    Circle:SUB Circle(Xpos,Ypos,Radius)
1700    COM /Scale/ Sc,INTEGER X,Y
1710    MOVE X*Xpos*Sc,Y*Ypos*Sc
1720    POLYGON Radius*Sc,16,16
1730    SUBEND

1890    ! Creates a label in the active IBASIC partition
1891    ! Text$ is the alphanumeric label
1892    ! Xpos,Ypos is the position of the label
1893    ! Lorg references the label orientation to Xpos,Ypos
1894    ! Ldr is the angle in which the label will be drawn
1895    ! Pen is pen number (0 erases)
1896    ! Sc is a scaling factor for the figure being drawn
1900    Label:SUB Label(Text$,Xpos,Ypos,Size,Lorg,Ldr,Pen)
1910    COM /Scale/ Sc,INTEGER X,Y
1920    LORG Lorg
1930    LDIR Ldr
1940    CSIZE Size*Sc,1
1950    MOVE X*Xpos*Sc,Y*Ypos*Sc
1960    PEN Pen
1970   LABEL Text$
1980   PEN 1
1990   SUBEND
2000   !

The following program displays a "HELP" screen and demonstrates many of the techniques discussed so far. Running this program produces the screen display shown in Figure 7-5.

10   DIM A$(58),String$(1000)
20   ASSIGN @Hp8711 TO 800
30   OUTPUT @Hp8711:"DISP:PROG FULL;*WAI"
40   GINIT
50   GCLEAR
60   MOVE 0,89
70   RECTANGLE 200,14
80   PRINT TABXY(24,2);"HELP"
90   OUTPUT A$;"This program demonstrates how to print several"
100  String$=String$&A$
110  OUTPUT A$;"lines of text at one time. This method offers"
120  String$=String$&A$
130  OUTPUT A$;"the fastest possible print speed."
140  String$=String$&A$
150  PRINTER IS CRT;WIDTH 1000 ! Prevent auto cr/lf
160  PRINT TABXY(1,5);String$
170  END

```
HELP
This program demonstrates how to print several
lines of text at one time. This method offers
the fastest possible print speed.
```

Figure 7-5. "HELP" program output

7-8 Graphics and Display Techniques
Graphics Exceptions

The following graphics commands do not conform to the keyword description found in the HP Instrument BASIC Users Handbook:

VIEWPORT - Does not create isotropic units that are physically square. Does not soft clip the display area.

CLIP - The analyzer does not support graphics clipping.

SHOW - Does not create isotropic units.

POLYLINE, POLYGON, RECTANGLE, Rplot - The analyzer does not support the FILL or EDGE options. Also see next paragraph.

GRID, RECTANGLE, POLYGON, and POLYLINE scaling differences

When the display is initialized using GINIT, the display will be scaled to a height of 100 GDU’s and a width of 245 GDU’s.

The ratio is 2.453 and the pixel height-to-width ratio is fixed at 1.79 (non square pixels). This can cause scaling difficulties if not well understood, and will produce different results than is seen on HP BASIC computers or workstations. The following examples should help clarify some scaling issues.

After GINIT, performing a GRID 10,10 command will produce a grid array 10 high and 24.5 wide. The individual grids will be rectangular (taller than wide). To produce square grids, perform a GRID 10*1.79,10 command. This will produce square grids; 10 high and just under 14 wide. If you move the starting point to approximate center (MOVE 120,50) and request a square 55 wide by 55 high (RECTANGLE 55,55), the analyzer will automatically scale this so as to appear square. The width will be 55 GDU’s but the height will be 55/1.79 or 30.7 units high. This will appear square and is quite a different result than would be obtained by attempting to plot a “square” 55 units on each side; this would instead, produce a rectangle.

A similar scaling is done with the POLYGON command. If a POLYGON 80 command is given, the analyzer will produce a circle with a horizontal radius of 80, but with a vertical radius of 44.7 GDU’s; even so, it will appear circular.

The following is a simple rule to remember with GINIT values (or the equivalent WINDOW ratio) on the analyzer: The analyzer will produce circles with the POLYGON/POLYLINE command and squares with the RECTANGLE command (assuming equal x,y) in all cases. However, the radius or width (in GDU’s) will be accurate only in the horizontal axis and will be 1.79 times LESS in the vertical axis.

Try this simple program to demonstrate the above examples. Un-comment line 60 and comment out line 50 to show the difference in the two GRID statements. The rectangle may be hard to see since it will partially lie on a gridline; its lower left corner is at the centered dot.

```
10  ASSIGN @Hp8711 TC 800
20  OUTPUT @Hp8711,";DISP:PROG FULL"
30  GINIT
40  GCLEAR
50  GRID 10,10       ! makes rectangular grids
60  ! GRID 10*1.79,10 ! makes square grids
```

Graphics and Display Techniques  7-9
70  MOVE 120,50  ! move to center
80  POLYGON 1  ! make small dot
90  RECTANGLE 55,55  ! makes square
100  POLYGON 80
110  END

Labeling with Different Partitions

The LABEL command may be used to label graphs, however, the following should be noted. Labels that may be of the correct size for a full screen partition will appear half as big if a GINIT is performed after the analyzer has been set to either the upper or lower half partition. This is because the CSIZE command scales according to display height, not width. Since the display height is one-half, the character size will also be one-half. Labels that are scaled properly for full screen displays will not be scaled properly for half screen displays and vice-versa.
SCPI Graphics Commands

In addition to the commands described earlier in this chapter, there are several SCPI mnemonics that can be used to create graphics and messages on the display of the analyzer.

These commands are instrument specific mnemonics, not standard IBASIC commands. They are also different from the previously described IBASIC commands in that they do not require an IBASIC display partition. This means that they can be used to write or draw directly to a measurement window.

These commands, listed in Table 7-2 are SCPI mnemonics and are programmable from an external controller as well as from IBASIC. The commands are of the form

\[ \text{DISPlay:WINDow}[1|2|10]:\text{GRAPHics:<command>}. \]

The number specified in the WINDow part of the command selects where the graphics are to be written.

- WINDow1 draws the graphics to the channel 1 measurement window.
- WINDow2 draws the graphics to the channel 2 measurement window.
- WINDow10 draws the graphics to an IBASIC display partition.

**Tip**

When SCPI graphics commands are used to write directly to a measurement window they write to the static graphics plane (the same plane where the graticule is drawn). There is no sweep-to-sweep speed penalty once the graphics have been drawn.

For more information about the analyzer’s user graphics commands, refer to Chapter 7 of the *Programmer's Guide*. Refer also to the example program titled “GRAPHICS” in Chapter 11 of the Programmer's Guide.
Interfacing with External Devices

This section describes the techniques necessary for programming the HP-IB interface. It describes how this interface works and how to use it to control or interface with systems containing various HP-IB devices. It also describes how to interface with external devices using the serial and parallel interfaces.

The HP-IB interface is Hewlett-Packard's implementation of the IEEE-488.1 Digital Interface for Programmable Instrumentation. The acronym HP-IB stands for "Hewlett-Packard Interface Bus," and is often referred to as the "bus." The interface is easy to use and allows great flexibility in communicating data and control information between an HP Instrument BASIC program and external devices.

IBASIC is an HP-IB instrument controller residing inside an instrument. It uses the instrument's HP-IB interface for external communication and an internal HP-IB interface to communicate with the instrument. This unique arrangement presents a few differences between IBASIC's implementation of HP-IB control and HP BASIC controllers. A description of the interaction of IBASIC with the host instrument and the external HP-IB interface is given in the section entitled "The IBASIC HP-IB Model", later in this chapter.

Communication with Devices

HP-IB Device Selectors

Since the HP-IB allows several devices to be interconnected, each device must be uniquely identified. Specifying the select code of the HP-IB interface (such as 7 or 8) to which a device is connected is not enough to uniquely identify each specific device on the bus.

Each device on the bus has a primary address that identifies it. This address can be set by the user. It must be unique to allow individual access of each device. When a particular HP-IB device is to be accessed, it must be identified with both its interface select code and its bus address.

The interface select code is the first part of an HP-IB device selector. IBASIC programs run inside an instrument and communicate with it over an internal bus (interface select code 8). IBASIC programs can also communicate with external devices using the instrument's HP-IB interface (select code 7).

The second part of an HP-IB device selector is the device's primary address, an integer in the range of 0 through 30. For example, to specify the device on the interface at select code 7 with a primary address of 22, use device selector 722. Secondary HP-IB addressing is
also supported for those devices requiring it. These devices will have at least 5-digit service selection such as 72201.

Since the analyzer is the only device on the internal interface, its primary address on that interface is arbitrary and the instrument will respond to any primary address with a select code equal to 8 (e.g., 800, 811, 822, etc.).

---

**Note**

Each device's address must be unique. The analyzer is shipped from the factory with a primary address of 16. No other device on the bus should use the same address.

The procedure for setting the address of an HP-IB device is given in the installation manual for each device. To set the address of the analyzer, use the softkeys in the [SYSTEM OPTIONS] {HP-IB} menu, or the SCPI mnemonic `SYST:COMM:GPIB:ADDR`.

---

**Moving Data Through the HP-IB**

Data is output and entered into the program through the HP-IB with the `OUTPUT` and `ENTER` statements, respectively. The only difference between the `OUTPUT` and `ENTER` statements for the HP-IB and those for other interfaces is the addressing information within HP-IB device selectors.

The following examples show several different syntax styles which you can use.

```
100  Hpb=7
110  Device_addr=22
120  Device_selector=Hpb * 100 + Device_addr
130  !
140  OUTPUT Device_selector;"F1R7T2T3"
150  ENTER Device_selector;Reading

320  ASSIGN @hpb_device T0 702
330  OUTPUT @hpb_device;"Data message"
340  ENTER @hpb_device;Number

440  OUTPUT 800;"SCUR1:POW -10 dBm"
480  ENTER 724;Readings(*)
```
General Structure of the HP-IB

Communications through the HP-IB are made according to a precisely defined standard (the IEEE 488.1 standard). The rules set by IEEE 488.1 ensure that orderly communication takes place on the bus. For more information about the structure of the HP-IB and the IEEE 488.1 standard, refer to the Tutorial Description of the Hewlett-Packard Interface Bus.

Devices that communicate over the HP-IB perform one or more of the following three functions.

- Talk — send data over the bus
- Listen — receive data over the bus
- Control — control the exchange of data on the bus

The System Controller

The controller is a device that has been designated to control the communication occurring on the bus. It specifies which device talks, which device listens and when the exchange of data takes place.

An HP-IB system can have more than one device with the ability to control the bus, but only one of these devices is allowed to control the exchange of data at any given time. The device that is currently controlling the exchange of data is called the Active Controller.

One device must be able to take control of the bus even if it is not the active controller. The device designated as the System Controller is the only device with this ability. To designate the analyzer as the system controller use the System Controller softkey in the SYSTEM OPTIONS HP-IB menu.

The system controller is generally designated before running a program and should not be changed under program control. An exception to this is when an IBASIC program is running on the analyzer’s internal controller. If the IBASIC program controls other HP-IB devices, the analyzer must be designated as the system controller.

A SCPI mnemonic SYST:COMM:GPIOB:CONT <ON|OFF> can be used to make the analyzer the system controller. Program execution should be carefully synchronized, using the Operation Complete command (*OPC?) and waiting for a reply before any OUTPUT 7xx command is sent. (Refer to the “Synchronizing the Analyzer and a Controller” chapter in the Programmer’s Guide for more information on the *OPC? command.)

Using the Serial and Parallel Ports

The analyzer has two additional ports that can be used to control peripherals, material handlers or other devices. Active control of the HP-IB interface is not needed when these ports are being used. These ports are a parallel port and a serial port for use with hardcopy output to non-HP-IB printers and plotters.

In addition to the serial and parallel ports, there are also two BNC connectors on the rear panel of the analyzer. These connectors provide access (using TTL signal levels) to two programmable bits.

- Limit Test TTL bit — indicates the results of a pass/fail limit test
- User TTL bit — to be used as needed (for example to use with a foot pedal)
Using the Analyzer Ports in IBASIC programs

IBASIC can directly control the serial port, the parallel port, the Pass/Fail TTL bit, and the User bit without using HP-IB commands with READIO and WRITEIO. READIO and WRITEIO are faster than HP-IB commands.

**Writeable Ports**

**WRITEIO 15,0;A**
Outputs 8-bit data to the Cent..D0 through D7 lines of the Centronics port. Cent..D0 is the least significant bit, Cent..D7 is the most significant bit. Sets Printer..select signal high (de-select). Checks Centronics status lines for:
- Out of Paper
- Printer Not on Line
- BUSY
- ACKNOWLEDGE

**WRITEIO 15,1;A**
Sets/clears the “user” bit according to the least significant bit of A. A least significant bit equal to 1 sets the user bit high. A least significant bit of 0 clears the user bit.

**WRITEIO 15,2;A**
Sets/clears the limit pass/fail bit according to the least significant bit of A. A least significant bit equal to 1 sets the pass/fail bit high. A least significant bit of 0 clears the pass/fail bit.

**WRITEIO 15,3;A**
Outputs 8-bit data to the Cent..D0 through D7 lines of the Centronics port. Cent..D0 is the least significant bit, Cent..D7 is the most significant bit. Sets Printer..select signal high (de-select). Does not check Centronics status lines.

**WRITEIO 9,0;A**
Outputs a byte to the serial port. The byte is output serially according to the configuration for the serial port. (See above.)

**Readable Ports** [ I=READIO(A,B) ]

**READIO 9,0**
Reads the serial port.

**READIO 15,0**
Reads the 8-bit data port, Cent..D0 through D7.

**READIO 15,1**
Reads the user bit.

**READIO 15,2**
Reads the limit test pass/fail bit.

**READIO 15,10**
Reads the 8-bit status port:
- D0 = Cent..acknowledge
- D1 = Cent..busy
- D2 = Cent..out_of_paper
- D3 = Cent..on_line
- D4 = Cent..printer_err

An example program, REPORT, demonstrating peripheral control over the parallel port is provided in Chapter 11, “Example Programs.”

Refer to “Automating Measurements” in the *Users Guide* for further explanation and examples of how to access the analyzer’s I/O ports.

8-4 Interfacing with External Devices
General Bus Management

The HP-IB standard provides several mechanisms that allow managing the bus and the devices on the bus. Here is a summary of the IBASIC statements that use these control mechanisms.

**ABORT** — abruptly terminates all bus activity and resets all devices to their power-on HP-IB states.

**CLEAR** — sets selected (or all) devices to a pre-defined, device-dependent HP-IB state.

**LOCAL** — returns selected (or all) devices to local (front panel) control.

**LOCAL LOCKOUT** — disables selected (or all) devices' front panel controls.

**REMOTE** — puts selected (or all) devices into their device-dependent, remote modes.

**SPOLL** — performs a serial poll of the specified device (which must be capable of responding).

**TRIGGER** — sends the trigger message to a device (or selected group of devices).

These statements (and functions) are described in the following discussion. However, the actions that a device takes upon receiving each of the above commands are, in general, different for each device. For external devices, refer to the particular device's manuals to determine how it will respond.

All of the bus management commands, with the exception of **ABORT**, require that the program be the active controller on the interface. A running IBASIC program is always active controller on the internal interface (select code 8). For the program to be active controller on the external interface (select code 7), the instrument must either be set as system controller or have control passed to it from an external controller. The program automatically assumes the controller status of the host instrument. For more information refer to “The IBASIC HP-IB Model” section later in this chapter.

**Note**

In this section the term **Host Instrument** refers to the instrument where the IBASIC controller is located.
REMOTE

Most HP-IB devices can be controlled either from the front panel or from the bus. If the device's front panel controls are currently functional, it is in the Local state. If it is being controlled through the HP-IB, it is in the Remote state. Unless operating in the Local Lockout mode, each HP-IB device has method (usually a key) to return itself to Local (front panel) control.

When the analyzer is being controlled by a program running on an external controller, the Return to Local softkey is always available to return the analyzer to Local control.

The Remote message is automatically sent to all devices whenever the system controller is powered on, reset, or sends the Abort message. A device also enters the Remote state automatically whenever it is addressed. The REMOTE statement also outputs the Remote message, which causes all (or specified) devices on the bus to change from local control to remote control. The host instrument must be designated as the system controller before an IBASIC program can execute the REMOTE statement on select code 7.

HOST INSTRUMENT

The REMOTE statement has no effect on the host instrument since it is always in remote control whenever an IBASIC program is running. Specifying the internal interface in a REMOTE statement will not generate an error, but will have no effect.

LOCAL LOCKOUT

The Local Lockout message effectively locks out the “local” switch present on most HP-IB device front panels. It maintains system integrity by preventing a user from interfering with system operations by pressing buttons. As long as Local Lockout is in effect, no bus device can be returned to local control from its front panel.

The Local Lockout message is sent by executing the LOCAL LOCKOUT statement. This message can be sent to all devices on the external interface by specifying the bus address (7). Specifying a single address on the bus (i.e. 722) sends the command to only the device at that address. The Local Lockout message is cleared when the Local message is sent by executing the LOCAL statement. However, executing the ABORT statement does not cancel the Local Lockout message.

HOST INSTRUMENT

The Local Lockout message is not supported for the host instrument since front panel control is always necessary in order to pause or abort the program. Specifying the internal interface in a LOCAL LOCKOUT statement will not generate an error, but will have no effect.
LOCAL

During system operation, it may be necessary for an operator to interact with one or more external devices. For instance, an operator might need to work from the front panel to make special tests or to troubleshoot. It is also good systems practice to return all devices to local control when remote-control operations are complete. Executing the LOCAL statement returns the specified devices to local (front panel) control.

If primary addressing is specified, the Go-to-Local message is sent only to the specified device(s). However, if only the interface select code is specified (LOCAL 7), the Local message is sent to all devices on the external interface and any previous Local Lockout message (which is still in effect) is automatically cleared.

Host Instrument

The LOCAL statement has no effect on the host instrument since it is always in remote control whenever an IBASIC program is running. Specifying the internal interface in a LOCAL statement will not generate an error.

TRIGGER

The TRIGGER statement sends a Trigger message to a selected device or group of devices. The purpose of the Trigger message is to initiate some device-dependent action; for example, it can be used to trigger a digital voltmeter to perform its measurement cycle. Because the response of a device to a Trigger message is strictly device-dependent, neither the Trigger message nor the interface indicates what action is initiated by the device.

Specifying only the interface select code outputs a Trigger message to all devices currently addressed to listen on the bus. Including a device address in the statement triggers only the device addressed by the statement.

Host Instrument

The TRIGGER statement is supported by the analyzer. Issuing a TRIGGER command will initiate a single sweep assuming the analyzer is in TRIGGER hold mode. TRIGGER is ignored if not in hold mode.

CLEAR

The CLEAR statement provides a means of “initializing” a device to its predefined device-dependent state. When the CLEAR statement is executed, the Clear message is sent either to all devices or to the specified device, depending on the information contained within the device selector. If only the interface select code is specified, all devices on the specified HP-IB interface are cleared. If primary-address information is specified, the Clear message is sent only to the specified device. Only the active controller can send the Clear message.

Host Instrument

The CLEAR statement is fully compatible on the internal interface.
ABORT

This statement may be used to terminate all activity on the external bus and return the HP-IB interfaces of all devices to reset (or power-on) condition. Whether this affects other modes of the device depends on the device itself. The IBASIC program must be either the active or the system controller to perform this function. If it is the system controller and has passed active control to another device, executing this statement causes active control to be returned. Only the interface select code may be specified; primary-addressing information (such as 724) must not be included.

Aborting the Internal Bus

ABORT is not supported for select code 8. Executing ABORT 8 will not generate an error.

HP-IB Service Requests

Most HP-IB devices, such as voltmeters, frequency counters, and network analyzers, are capable of generating a "service request" when they require the active controller to take action. Service requests are generally made after the device has completed a task (such as making a measurement) or when an error condition exists (such as a printer being out of paper). The operating and/or programming manuals for each device describe the device's capability to request service and conditions under which the device will request service. To request service, the device sends a Service Request message (SRQ) to the active controller. The mechanism by which the active controller detects these requests is the SRQ interrupt. Interrupts allow an efficient use of system resources, because the system may be executing a program until interrupted by an event’s occurrence. If enabled, the external event initiates a program branch to a routine which "services" the event (executes remedial action).

Setting Up and Enabling SRQ Interrupts

In order for an HP-IB device to be able to initiate a service routine in the active controller, two prerequisites must be met: the SRQ interrupt event must have a service routine defined, and the SRQ interrupt must be enabled to initiate the branch to the service routine.

The following program segment shows an example of setting up and enabling an SRQ interrupt.

```
100  Hpic=7
110   ON INTR Hpic GOSUB Service_routine
120    !
130   Mask=2
140   ENABLE INTR Hpic;Mask
```

Since IBASIC recognizes only SRQ interrupts, the value assigned to the mask is meaningless. However, a mask value may be present as a placeholder for compatibility with HP Series BASIC programs.

8-8  Interfacing with External Devices
When an SRQ interrupt is generated by any device on the bus, the program branches to the service routine when the current line is exited (either when the line's execution is finished or when the line is exited by a call to a user-defined function). The service routine, in general, must perform the following operations:

1. Determine which device(s) are requesting service
2. Determine what action is requested
3. Clear the SRQ line
4. Perform the requested action
5. Re-enable interrupts
6. Return to the former task (if applicable)

**Note**

The **ON INTR** statement must always precede the **ENABLE INTR** statement when the two are used in the same program.

---

**Servicing SRQ Interrupts**

The SRQ is a level-sensitive interrupt; in other words, if an SRQ is present momentarily but does not remain long enough to be sensed by the controller, an interrupt will not be generated. The level-sensitive nature of the SRQ line also has further implications, which are described in the following paragraphs.

**Example**

Assume that only one device is currently on the bus. The following service routine serially polls the device requesting service and clears the interrupt request. In this case, the controller does not have to determine which device was requesting service because only one device is present. Since only service request interrupts are enabled in IBASIC, the type of interrupt does not need to be determined either. The service is performed, and the SRQ event is re-enabled to generate subsequent interrupts.

```
500 Serv_rtn:  Ser_poll=SPOLL(@Device)
510 ENTER @Device;Value
520 PRINT Value
530 ENABLE INTR 7  ! Use previous mask.
540 RETURN
```

The IEEE standard states that when an interrupting device is serially polled, it is to stop interrupting until a new condition occurs (or the same condition occurs again). To "clear" the SRQ line, a serial poll must be performed on the device. By performing this serial poll, the controller acknowledges to the device that it has seen the request for service and is responding. The device then removes its request for service (by releasing SRQ).

If the SRQ line had not been released, the controller would have branched to the service routine immediately upon re-enabling interrupts on this interface. This is due to the level-sensitive nature of the SRQ interrupt.

Also note that once an interrupt is sensed and logged, the interface cannot generate another interrupt until the first interrupt is serviced. The controller disables all subsequent interrupts from an interface until a pending interrupt is serviced.
**Conducting a Serial Poll**

A sequential poll of individual devices on the bus is known as a Serial Poll. A byte of device-specific status is returned in response to a Serial Poll. This byte is called the “Status Byte” message and, depending on the device, may indicate an overload, a request for service, or a printer being out of paper. The particular response of each device depends on the device.

The SPOLL function performs a Serial Poll of the specified device; the program must currently be the active controller in order to execute this function.

Examples

```
ASSIGN @Device TO 700
Status_byte=SPOLL(@Device)

Spoll_724=SPOLL(724)
```

The Serial Poll is meaningless for an interface since it must poll individual devices on the interface. Therefore, primary addressing must be used with the SPOLL function.

**Passing and Regaining Control**

Active control of the bus can be passed between controllers using the PASS CONTROL command. The following statements first define the HP-IB interface’s select code and the new active controller’s primary address and then pass control to that controller.

```
100   Hp_ib=7
110   New_ac_addr=20
120   PASS CONTROL 100+Hp_ib+New_ac_addr
```

Once the new active controller has accepted active control, the controller passing control assumes the role of a non-active controller on the specified HP-IB interface. The concept of using pass control with IBASIC is discussed in the next section, “The IBASIC HP-IB Model.”
The IBASIC HP-IB Model

The fact that IBASIC resides in, and coexists with an instrument poses a large set of possible interactions, both internal to the instrument and externally with other controllers and instruments. This section defines the principal players and rules of order when IBASIC is running within the host instrument.

External and Internal Busses

There is physically only one HP-IB port and one HP-IB address for the analyzer. IBASIC has access to two HP-IB ports: the "real" external port (select code 7) and a "virtual" internal port (select code 8), through which it communicates with the analyzer.

The analyzer has only one output buffer, one input buffer and one set of status registers. Commands and data from both ports are placed in the same input buffer and data read out of both ports comes from the same output buffer. The instrument will not provide any kind of arbitration between an external controller and an IBASIC program.

The analyzer always behaves as if there is only one controller. If an IBASIC program is running, it is assumed to be the controller and therefore will receive all SRQs from the host instrument (via the internal port).

Service Request Indicators

An external controller may perform a serial poll (SPOLL) at any time without affecting a running IBASIC program. There are two Service Request Indicators (SRI) - one for the external port and one for the internal port. The internal SRI can only be cleared by an IBASIC program performing an SPOLL on device 800. The external SRI can only be cleared by an SPOLL from an external controller and can only be set when there is not an active IBASIC program.

The two SRI's will be set to their OR'd value when a program starts, and again when it finishes. This assures that any pending SRQ's can be serviced by the instrument's new controller.

The pausing or termination of a program will cause the Program Running bit in the Device Status register to go low. This can be used to generate an external SRQ. (For an example, see the DUALCTRL example in Chapter 11, "Example Programs.")
**IBASIC as the Active Controller**

The IBASIC program is always the active controller on the internal interface (select code 8). When a program starts running, the HP-IB controller status of the instrument is automatically passed to the program. For example, if the instrument is set as System Controller, a program running in the instrument automatically becomes system controller and active controller on the external bus and the instrument relinquishes active control. When the program stops, the instrument regains active control.

Also, if an instrument set as Talker/Listener is passed control from an external controller, any program running in the instrument becomes active controller on the external interface.

Thus, there are two cases where a program running in an instrument can be active controller on the external interface:

- When the host instrument is set as System Controller and the program has not passed control
- When the host instrument is set as Talker/Listener and the instrument has been passed control from an external controller.

**Passing Active Control to the Instrument**

The only way that the analyzer can gain active control of the external interface while a program is running is if the program is currently the active controller on select code 7 and passes control to the instrument. Normally, the active controller on the 7 bus can pass control to any device on the interface by using the statement

```
PASS CONTROL 7xx
```

where "xx" represents the address of the device on the bus. Because an IBASIC program does not interface with the host instrument over select code 7, a different method is used to pass control in this case. To pass active control of the external interface from an IBASIC program to the host instrument, use the statement

```
PASS CONTROL 8xx
```

where “xx” represents any two digit number from 00 to 99. This allows the instrument to control external plotters, printers and disk drives. When the instrument is finished with its HP-IB control activity, it automatically passes control back to the program.

---

**Note**

Control over the internal bus is used to govern access to the external bus. When the instrument is given control over the internal bus, it is actually given access to the external HP-IB hardware.
IBASIC as a Non-Active Controller

IBASIC programs are always the active controller on the internal interface. There are two cases where an IBASIC program does not have control of the external HP-IB interface:

- When the host instrument is set as Talker/Listener and active control has NOT been passed from an external device
- When the host instrument is set as System Controller and the program has passed control to either the host instrument or another device on the external interface

In both of these cases, the program cannot perform activities of any kind on the external interface.

Note
An IBASIC program cannot act as a device on the external bus. To communicate with an external controller, the IBASIC program must be active controller and the external controller must act as the device (see the "Interfacing with an External Controller" section that follows).

Interfacing with an External Controller

So far, we have discussed the ability to interface IBASIC programs with a network of external devices using the HP-IB. The idea of including an external controller in that network, and interfacing an IBASIC program with a program running in that computer presents some new possibilities.

External controller programs can interface with IBASIC programs (referred to as "internal programs") over HP-IB in two basic ways:

First, the two programs can pass data back and forth using simple OUTPUT and ENTER statements. This requires coordination of both the internal and external programs and also requires that the internal program be the active controller during the interaction. To get an internal program and an external program to work together successfully, you should have a good understanding of the HP-IB model, presented earlier in this chapter.

Second, the external program can make use of the extensive set of analyzer HP-IB commands that interface with IBASIC programs. These mnemonics fall under the subsystem PROGRAM and allow the external controller to remotely perform many of the IBASIC front panel activities. This includes the ability to run, stop, pause, continue and delete an internal program. You can also remotely query or set the values of numeric and string variables.

Also included in the analyzer HP-IB command set are commands that allow you to transfer programs and program data to and from the instrument. Programs can be transferred (uploaded and downloaded) between an external controller and the program buffer in the instrument, and data can be transferred between an external program and a non-running internal program by setting and querying internal program variables. These SCPI mnemonics are described in the Programmer’s Guide.

Also, refer to example programs included on the IBASIC Example Programs Disk: DUALCTRL, TRICTRL, UPLOAD and DOWNLOAD. These programs demonstrate using IBASIC with an external controller.
Synchronizing IBASIC with an External Controller

Using OUTPUT and ENTER statements

Commands sent to the analyzer with OUTPUT and ENTER statements from IBASIC and from the external controller at the same time must be synchronized by the programmer. These commands cannot be allowed to overlap. Overlapped commands sent from the external controller and IBASIC will result in unpredictable behavior or deadlocks.

For example:

If the external controller executes:

```plaintext
OUTPUT 716; "<command>"
```

and IBASIC simultaneously executes:

```plaintext
OUTPUT 800; "<command>"
```

the results are unpredictable.

To avoid overlapped commands, you must ensure that only the controller is allowed to send commands or only IBASIC is allowed to send commands at any one time. One possible method to avoid overlap is described below. For this method, when the respective controller is done sending commands, the other controller is informed. The alternate controller then may begin sending commands. After each set of commands is completed, the alternate controller is informed and given a signal to send commands to the analyzer. See example program TRICTRL in Chapter 11.

Using Status Information

Status information must also be synchronized between the IBASIC program and a program running on an external controller. The status information is shared between these programs. Commands which affect the status information should not overlap between the IBASIC program and the external controller.

For example:

From an external controller:

```plaintext
OUTPUT 716; "<command>; *OPC?"
ENTER 716; 0pc
```

From IBASIC, simultaneously execute:

```plaintext
OUTPUT 800; "*CLS"
```

may cause the external controller to not complete execution. The *CLS command clears status information which the external controller may be waiting for. The commands which affect status information include *OPC, *OPC?, *WAI, *CLS, *RST, *SRE, *ESE, and STAT:PRES.

8-14 Interfacing with External Devices
Design Rules

Design your IBASIC and External Controller with the following rules:

- Do not overlap commands between the external controller and IBASIC.
- Do not change status information which is expected by the alternate controller. Design programs such that status information does not overlap.

See the example program, TRICTRL, which implements a synchronization protocol between an external controller and two instruments running IBASIC programs.

Transferring Data Between Programs

Using OUTPUT and ENTER statements

All data sent from an external controller to the instrument’s external port is received by the instrument and not by any program running in it. Therefore, a non-active controller IBASIC program can never enter or output data via the external interface. This means that in order to pass data between an external controller and an internal program using OUTPUT and ENTER statements, the internal program must be given active control and the external controller must become the non-active controller. HP IBASIC for Windows and HP BASIC controllers have the ability to enter and output data via HP-IB while acting as a non-active controller.

Note

Moving data through the HP-IB and running a measurement in the host instrument at the same time can slow both operations significantly.

It is recommended that you do not perform these operations simultaneously.

One method of passing data between the two controllers is to set the instrument as Talker/Listener and run a program on the external controller that starts the IBASIC program and passes control to it. The IBASIC program can then output data to, and enter data from, the external controller. Two programs, that are listed in Chapter 11, “Example Programs,” demonstrate how to transfer data between an internal program and an external controller program. The first program, DATA_EXT, is run from an external controller. It assumes that a disk containing the corresponding IBASIC program DATA_INT is in the disk drive of the analyzer. It remotely loads the IBASIC program, starts it and then transfers active control to it. The IBASIC program DATA_INT, with active control of the interface, queries the external program for name of the drive to catalog, and then outputs the cataloged string to the external program and passes active control back. After receiving the catalog data, the external program goes into a loop (line 1080) executing a command that continues to generate an error until the host computer again becomes active controller when control is passed back.
Setting and Querying Variables

Another means of transferring data between an internal and an external program involves the ability to set and query internal program variables from an external program. The "PROG[:SELECTed]:NUMBER" and "PROG[:SELECTed]:STRING" mnemonics (and their query counterparts) are part of the analyzer HP-IB commands. The internal program must not be running when these commands are executed.

The command

```
PROG:NUMB < string >, < value >
```

sets the value of a numeric variable in the program. The command

```
PROG:STR < string >, < value >
```

sets the value of a string variable in the program. In both the PROG:NUMB and PROG:STR commands and queries, < string > is the variable name and must be string data (in quotes). In the PROG:STR command, < value > is also string data (in quotes).

Numeric and string parameters can also be queried. The query

```
PROG:NUMBER? < string >
```

returns the value of the specified numeric variable.

Arrays of REAL or INTEGER type may be sent or queried but arrays of strings are not allowed. Array elements are separated by commas.

Examples

```
OUTPUT 716; "PROG:NUMBER 'Test',99"

OUTPUT @ibasic; "PROG:STRING 'A$','String Data'"

OUTPUT 716; "PROG:NUMBER? 'Iarray(*)'"
```

The following program segment sends both numeric and string variable queries and enters the resulting data:

```
10  ASSIGN @Prog TO 716
20  OUTPUT @Prog; "FORM ASCII,3"
30  OUTPUT @Prog; "PROG:NUMB? 'Test'"
40  ENTER @Prog; Testval
50  PRINT "The value of the variable Test = "; Testval
60  OUTPUT @Prog; "PROG:STR? 'A$'"
70  ENTER @Prog; Str$
80  PRINT "A$ = "; Str$
90  END
```
Downloading and Uploading Programs

Programs can be transferred between an external controller and program memory using the HP-IB download command "PROG[:SELECTed]:DEFine" and its upload query "PROG[:SELECTed]:DEFine?". Programs that use these mnemonics are run in the external controller.

Downloading

Program data transferred (downloaded) from the external controller to the instrument is always transferred as an "arbitrary block." The arbitrary block may be a definite length or indefinite length block. The indefinite length block is by far the easiest and is simply a block of data that begins with the characters "#0" preceding the first line and ends with a line-feed character accompanied by an EOI signal on the HP-IB interface.

When using the mnemonic PROG:DEF to download program lines, the #0 must not be followed by a line-feed. Each program line must have a line number at its beginning and a line-feed at its end. To end the arbitrary block of program lines, a single line-feed must be output with the OUTPUT END parameter, which sends the EOI (End or Identify) signal on the HP-IB control lines.

Refer to Chapter 11, “Example Programs” for a listing of the example program DOWNLOAD.

Notice that the OUTPUT statement on line 460 is terminated with a semicolon. This suppresses the line-feed that would otherwise occur.

As each line of the program is downloaded it is checked for syntax.

If an error is found, the error message is displayed on the CRT and the line is commented and checked for syntax again. If it still causes an error (for example the line may be too long) the line is discarded.

Any lines that currently exist in the memory buffer will remain unless they are overwritten by downloaded program lines. This makes it easy to edit lines in an external controller and then download only the edited lines into an existing program. If you want to completely overwrite the current program in memory, you must delete the program first. This can be done remotely using the extended command PROG:DEL:ALL (see line 350).
Uploading

The mnemonic PROG:DEF? is used to upload a program from the program buffer. The entire program is then returned as a definite length arbitrary block. A definite length block starts with the "#" character followed by a single digit defining the number of following digits to read as the block length.

Refer to Chapter 11, "Example Programs" for a listing of the example program UPLOAD, which demonstrates an uploading routine run on an external controller.

The subroutine Openfile (lines 570 through 770) creates an ASCII file to save the uploaded program to. The number of 256 byte records declared in the CREATE ASCII statement (line 730) is simply the file size (declared in the definite block header) divided by 256. Line 720 accommodates any remainder in this calculation by increasing the file size number by one record if any remainder exists.

Although this simple method works for many uploaded programs, there may still be a problem with the file size caused by the OUTPUT statement in line 490. This is because every ASCII line in a LIF file contains a two byte length header and possibly one additional pad byte to make the length an even number of bytes. These extra bytes are not included in the definite length block header information. You can account for this extra overhead by allocating an extra 10 to 15 percent of space when you create the ASCII file. For example, the Openfile subroutine could be rewritten as:

```
570 SUB Openfile(@File,Filename$,Fsize)
680  ON ERROR GOTO Openerr
715  Fsize=Fsize+(Fsize*0.15)
720  IF Fsize MOD 256>0 THEN Fsize=Fsize+256
730  CREATE ASCII Filename$,Fsize DIV 256
```
Using Subprograms

Analyzer products shipped with the IBASIC option can run subprograms. The subprograms may be user-created or built-in.

User-Created Subprograms

You can use the LOADSUB keyword with subprograms of your own creation. LOADSUB enables you to append subprograms to other programs and is supported as described in the RMB manual. When using LOADSUB, keep in mind the following:

- Subprograms must be stored to files using the STORE keyword when first created.
- Subprograms may be stored from the external keyboard or from the front panel if the [File Type] format is BIN.
- BIN type files are generally not transportable between the analyzer and other development systems (only ASCII files are compatible with other systems).

Typical examples of LOAD/STORE:

From an external keyboard:

LOAD "MYFILE"
STORE "MYFILE"

From the front panel:

![Save/Recall Programs File Type BIN Save/Program](image)

Typical examples of LOADSUB:

LOADSUB subprogram_name FROM "filename"
LOADSUB ALL FROM "filename"

User-created subprograms are appended to the end of the BASIC program currently stored in the EDIT buffer.
Built-In High-Speed Subprograms

You can use LOADSUB to access pre-compiled routines stored as instrument firmware in internal memory. Any IBASIC program running on the analyzer can access these subprograms; programs running on external computers cannot. The external program must use the equivalent code listed in the table below in place of a built-in subprogram.

IBASIC programs which use the built-in subprograms are simpler and run faster. For example, most data transfer operations run twice as fast when using the built-in subprograms; math operations run many times faster. Built-in subprograms are stored in memory designated as “MEM,0,0”.

To access a subprogram, the subprogram first must be loaded into the main program using the LOADSUB keyword. The LOADSUB keyword requires a filename be specified from which to load the subprogram. Three built-in files are “XFER”, “MATH”, and “RPG”.

- “XFER” file adds support to transfer trace data between the instrument and the IBASIC program.
- “MATH” file adds high speed support for complex array operations.
- “RPG” file adds fast RPG (rotary pulse generator — front panel knob) response for markers.

LOADSUB <Subprogram name> FROM <Filename:MEM,0,0> loads the named subprogram from the built-in file “FILENAME”.

LOADSUB ALL FROM <Filename:MEM,0,0> loads all the subprograms in the named built-in file “FILENAME”. See the following table for subprogram names within the files “XFER”, “MATH”, and “RPG”.

9-2 Using Subprograms
## Built-in Subprogram Description (Filenames found in :MEM,0,0)

|          |                                   | 2=Actv MKR & LABELS |
Example Programs

1
10 LOADSUB Read_fdata FROM "XFER:MEM,0,0"

Example use of built in subprograms
Appends Read_data sub program to end of this program.
This subprogram can now be called.

20
30
40
50 REAL Trace_array(1:201)
60 Read_fdata(1,Trace_array(*))
70 LOADSUB ALL FROM "MATH:MEM,0,0"

Reads Channel 1 data into Trace_array(*)
Appends all math subprograms defined in "MATH" to the end of this program.

80 END
90 SUB Read_fdata(INTEGER Chan,REAL A(*))
100 SUB Cmplx_mag(REAL Cdata(*),Mag(*),INTEGER Sz)
110 SUB Cmplx_arg(REAL Cdata(*),Arg(*),INTEGER Sz)
120 ...

Read real formatted data.
Mag of complex array.
Arg of complex array.

Note
Built in subprograms cannot be edited since they are compiled and built into the firmware. However, any subprogram can be deleted by the DELSUB keyword support in revision 2 IBASIC.

RUNTIME Built in subprogram Errors

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8,9,16</td>
<td>Improper or inconsistent dimensions found which specify array size. Using the wrong number of subscripts when referencing an array element.</td>
</tr>
<tr>
<td>983</td>
<td>Wrong type or number of parameters. An improper parameter list for a machine resident function.</td>
</tr>
</tbody>
</table>

Avoiding Multiple Loads of Subprograms

To avoid multiple LOADS of a subprogram which has already been loaded, the following example may be used.

10 ON ERROR GOTO 30
20 DELSUB Read_fdata
30 LOADSUB Read_fdata FROM "XFER:MEM,0,0"
40 OFF ERROR
IBASIC Keyword Summary

This chapter summarizes the HP Instrument BASIC keyword implementation in the analyzer. Table 10-1 is alphabetical. It indicates the type of support for each entry and notes exceptions, if any. Exceptions are major differences between the keywords descriptions in the “HP Instrument BASIC Language Reference” and their implementation in the analyzer. When differences are too extensive to be summarized, see the “HP Instrument BASIC Language Reference.”

Table 10-2 contains the same information as Table 10-1, but is organized by category.

Example Programs

Example Program Summaries

This chapter contains listings of the example programs referred to throughout this manual. These programs are all available on the IBASIC Example Programs Disk that accompanies this manual.

In addition to these example programs, there are two additional disks of examples for the analyzer. These disks are the Example Programs Disk — DOS Format and the Example Programs Disk — LIF Format. These disks are included with the network analyzer when it is delivered. All the programs on these disks are designed to run on the analyzer's internal IBASIC controller.

The example programs on the IBASIC Example Programs Disk, some of which are listed in this chapter, include the following:

**DATA_EXT — Data transfer between internal and external programs**

This program is designed to run on an external controller — either HP IBASIC for Windows running on a PC or HP BASIC running on an HP workstation.

This program demonstrates how to transfer data from an IBASIC program running on the analyzer to an HP BASIC or IBASIC program running externally. It loads a program into the HP 8711, runs it, sets a variable and then gives it control of the bus. This program then acts as a device on the bus (sending and receiving data).

**DATA_INT — Data transfer between internal and external programs**

This program is designed to run on the analyzer's internal IBASIC controller.

This program demonstrates how to transfer data to and from an external controller. In this example a catalog listing is transferred from the analyzer to the external controller. A numeric variable value is also downloaded from the external controller to the analyzer's program.

**DOWNLOAD — Download program to analyzer**

This program demonstrates how to download an IBASIC program to the analyzer. It is designed (in HP BASIC or HP IBASIC for Windows) to run on an external workstation or PC.
DRAW871X — Drawing setup diagrams

This program draws the network analyzer and a device under test to the full screen IBASIC display partition. The drawing can be scaled to fit the application. This program uses the analyzer’s graphics commands for drawing. To use the IBASIC drawing commands, see the “BARCODE” program.

DUALCTRL — Two controller operation

This program demonstrates how the external controller and HP IBASIC can work together. It is designed to run on an external controller (in HP BASIC or HP IBASIC for Windows). The program downloads an IBASIC program to the analyzer and runs it twice. After each run, two program variables are read from the analyzer and displayed.

REPORT — Using the parallel port

This program uses the analyzer to generate a report, making a hardcopy on a printer connected to the parallel port. It uses a subprogram to send the output to the parallel port one line at a time. Before using this program, be sure that your printer is configured to ignore the Printer_select Centronics signal, since the WRITE10 command does not assert this signal.

TRICTRL — External controller with local IBASIC controllers

This example program demonstrates how an external controller can be used with two instruments running IBASIC. Run this program on an external controller. Connect two instruments via HP-IB cables to the external controller. Set one instrument to address 16, set the other instrument to address 18.

This program insures that only the analyzer or the local IBASIC is sending SCPI commands at one time. This is one possible implementation of synchronizing the analyzer and a controller. Refer to “Automating Measurements” in the User’s Guide.

The external controller is responsible for downloading the IBASIC program to each analyzer. The external controller sets the status reporting to send a SRQ whenever a user requested service request occurs.

When all instrument configuration has completed, the external controller sends a “run program” command to each analyzer and then goes into an idle loop. The external controller remains in the idle loop until either instrument sends an SRQ.

While the external controller is idle, each instrument can freely send various SCPI commands. Each instrument may ask for service by triggering an SRQ. Once a SRQ has been triggered, the instrument must remain in an idle loop, until the external controller indicates it is done servicing the SRQ. This is done using the program variable “Ctrlr_flag”. The flag is cleared when the external controller is done and has returned to its idle loop.
UPLOAD — Upload program from analyzer

This program uploads the IBASIC program in the analyzer’s program buffer to an ASCII file on the external controller’s current mass storage device.

USERBEG — Set up user-defined User BEGIN softkeys

This program creates User BEGIN softkeys which allow the user to Save or Recall one of two instrument states, set the marker to maximum, set the scale/div, and compute some measurement statistics at the marker.

USERBEG1 — The default User BEGIN program

The default User BEGIN program is created automatically when there is no IBASIC program installed. In this default program, softkey 3 is defined to be the marker-to-max function; softkey 4 prompts the user for a title, and also enables the clock. You may edit this program to change the functions you need.

USERBEG2 — Fast recall of instrument states

This example program demonstrates the fast recall of previously defined instrument states. The instrument states SETUP1, SETUP2, and SETUP3 must have been previously saved to the analyzer’s internal non-volatile RAM disk. Load the program into the analyzer. Then press the BEGIN key. Enable the user-defined BEGIN by pressing User BEGIN ON. When User BEGIN is enabled, the BEGIN softkeys will be labeled “Setup1,” “Setup2,” and “Setup3.” To recall each setup, select the appropriate softkey.

USER.Bit — Using the USER bit

This program demonstrates how to read and write to the USER bit. The USER bit is a TTL signal accessible by a BNC connector on the analyzer’s rear panel. IBASIC’s graphics commands are used to draw the USER bit value to the display.

USERKEYS — Customized softkeys

This program provides an example of how the analyzer’s softkeys can be customized. The example demonstrates how to set up six instrument states, store them to the analyzer’s internal memory, and setup two interactive softkey menus to choose between them.
BARCODE, STATS, DATALOG — Bar Code Programs

You may use bar code readers to simplify your measurement setups. The HPCK-1210 KeyWand scanner or compatible bar code scanner will work with the analyzer. Connect your bar code scanner to the DIN keyboard connector. You may connect a keyboard or other DIN key input device in parallel with the bar code scanner. The bar code scanner will work in place of, or in addition to, your keyboard.

The INPUT statement is used to read the bar code from the scanner. When the input statement is encountered, the program will wait until the user has completed an input. The input is completed whenever a carriage return is received from the keyboard or a bar code has been successfully scanned by the bar code scanner.

The following three programs, designed to run on the analyzer's internal IBASIC controller, demonstrate the use of bar code scanner applications as well as other useful applications. While a bar code scanner is useful in demonstrating these programs, it is not required; one can simply press ENTER and the program will input default values. Sample bar codes are provided for experimentation at the end of this chapter.

The three programs are as follows:

BARCODE - This program demonstrates basic bar code scanning to select one of three filter setups depending upon what is scanned. RF stimulus is set and response limits are read, set and tested for each device. Depending upon result, the program prints “PASS” or “FAIL” on the CRT. Most useful in this program is a subprogram to draw an analyzer representation on the CRT. This code can be re-used in any user application that may require a guided setup.

The analyzer image (and DUT image) can be both scaled to any size, and offset in the X or Y axis as required. This is an excellent program to familiarize yourself with graphic routines using IBASIC graphics commands.

STATS - This program first reads a DUT bar code and sets the RF stimulus accordingly. It then displays a running average of all similar devices and constantly updates the display with both the current DUT and the current average of all devices tested so far. Also demonstrates the use of two of the built-in CSUB routines for reading and writing trace data from/to the analyzer.

DATALOG - This program will very quickly store measured trace data for one of three filters to internal analyzer memory in a format that can be read by spreadsheet programs for further analysis. Because the data is stored to RAM, the time delay inherent with disks is not an issue; trace data can be stored in a fraction of a second. With 101 data points per trace selected, the internal memory will hold over 200 device test results. At this point, the program automatically transfers the data to disk. Of course, more data points will take longer to store and fill the memory sooner. The program will read the bar code and select the stimulus accordingly. It then measures the device and upon request, stores it under a unique name dependent upon model number and serial number. Once the internal memory is full, or at any user requested time, all trace data is transferred to disk.
ADJ_110 — Automated procedure for service adjustment #110 (B* amplitude correction)

This program is provided as a servicing tool to automate the B* adjustment routine using IBASIC instead of using an external controller. Description of this program is provided in the adjustment portion of the service manual. Because this program was not intended to be an example program and due to its length (>1200 lines), the program listing is not provided here. However, there are several routines that may be useful in other applications. The following subprograms and functions may be of particular interest.

FNSelsoftkey$ A routine that displays a user defined message and allows the operator to select one of seven possible softkeys.

FNSelsoftkey$ A routine that allows selection of one of many possible choices by scrolling an arrow down the list of choices. The number of choices may exceed one screen. The front panel hard keys or knob can be used for scrolling. In addition, user defined softkeys can also be chosen. The user has the option of using the front panel keyboard or an external AT style keyboard. With a slight modification, described within the code, this routine can also be used on an HP RMB controller (e.g. an HP 9000 Series 300 computer).

FNYes A simple program that displays a user defined question and allows the user to select a YES or NO answer via the softkeys. Returns the number 1 for YES and 0 for NO.

Softpause Another simple routine that displays a user defined message and waits for the operator to press a RESUME softkey.

Note These routines require the Beeper and/or the Clear_screen subprograms which are also part of this program. However, both can be replaced with their IBASIC equivalent commands (BEEP and CLEAR SCREEN).
DATA_EXT — Data transfer between internal and external programs

10  !------------------------------------------------------------
20  !
30  ! BASIC program: DATA_EXT - Data transfer (external)
40  !
50  ! This program demonstrates how to transfer data from
60  ! an IBASIC program running on the HP 8711 to an
70  ! HP BASIC program (or an IBASIC program running
80  ! externally). This program was designed to run on a
90  ! computer or PC. It loads a program into the HP 8711,
100  ! runs it, and then gives it control of the bus.
110  ! This program then acts as a device on the bus;
120  ! sending and receiving data.
130  !
140  ! Before running this program, a disc with the program
150  ! 'DATA_INT' should be in the HP 8711's internal drive.
160  !
170  !------------------------------------------------------------
180  !

TRICTRL — External controller with local IBASIC controllers

! BASIC program: TRICTRL - Three controller operation
! One controller, Two IBASIC instruments
! This program is designed to run on an external
! controller. It demonstrates how the external
! controller and multiple instruments running IBASIC
! programs can be synchronized to work together.
! Run this program on an external controller. Two HP871x
! are needed. Set one HP871x to address 16. Set the
! other to address 18. Connect HP-IB cables between
! the controller and the two analyzers.
! The program downloads IBASIC programs to two HP 871Xs,
! then runs each program. Pressing softkey 1 on either
! instrument triggers a sweep. Pressing softkey 3 on
! either instrument will trigger an SRQ. The controller
! will poll the instrument over the HP-IB bus, determine
! which instrument has requested service, log the SRQ,
! and release the instrument for more measurements by
! setting the IBASIC variable Ctrl_flag.
! Initialize the variables for the interface select
! code and the HP-IB address of the HP 871X.

USERBEG — Set up user-defined User BEGIN softkeys

10 !Filename: USERBEGIN
20 !
70 !
80 ! Description: Program to set up the User Begin softkeys.
90 !
100 ! A) This program creates User Begin softkeys which allow
110 ! the user to: Save or Recall one of two instrument
120 ! states, set the marker to maximum, set the scale/div,
130 ! and compute some measurement statistics at the marker.
140 !
150 ! B) In order to run this program, do the following -
160 ! 1) Load this program into the 871x
170 ! 2) Press the "BEGIN" (hardkey) and the "User Begin
180 ! on/OFF" (softkey).
190 ! 3) The "User Begin" function is now enabled (which runs
200 ! this program). This program re-define the softkeys
210 ! displayed whenever the BEGIN hardkey is pressed. The functions
220 ! performed by these softkeys are defined by this
230 ! program. Note that all front panel keys in the
240 ! analyzer are active (as if there were no program running).
250 ! 4) Use the instrument as you normally would. However,
260 ! then the BEGIN hardkey is pressed, the menu defined
270 ! by this program will be displayed instead of the usual
280 ! BEGIN softkeys, until the "User Begin ON/off" (softkey
290 !) is pressed, turning off the "User Begin" mode.
300 !
