HP 8901B
MODULATION ANALYZER
Operation and Calibration Manual

SERIAL NUMBERS

This manual provides complete information for instruments with serial-number prefixes:
2314A to 2912A and all MAJOR changes that apply to your instrument.

rev. 01FEB91

Information for MAJOR changes is also provided for instruments with serial-number prefixes not listed in the above range.

For additional important information about serial numbers, refer to “INSTRUMENTS COVERED BY THIS MANUAL” in Section 1.

CERTIFICATION

Hewlett-Packard Company certifies that this product met its published specifications at the time of shipment from the factory. Hewlett-Packard further certifies that its calibration measurements are traceable to the United States National Bureau of Standards, to the extent allowed by the Bureau’s calibration facility, and to the calibration facilities of other International Standards Organization members.

WARRANTY

This Hewlett-Packard instrument product is warranted against defects in material and workmanship for a period of one year from date of shipment. During the warranty period, Hewlett-Packard Company will at its option, either repair or replace products which prove to be defective.

For warranty service or repair, this product must be returned to a service facility designated by HP. Buyer shall prepay shipping charges to HP and HP shall pay shipping charges to return the product to Buyer. However, Buyer shall pay all shipping charges, duties, and taxes for products returned to HP from another country.

HP warrants that its software and firmware designated by HP for use with an instrument will execute its programming instructions when properly installed on that instrument. HP does not warrant that the operation of the instrument, or software, or firmware will be uninterrupted or error free.

LIMITATION OF WARRANTY

The foregoing warranty shall not apply to defects resulting from improper or inadequate maintenance by Buyer, Buyer-supplied software or interfacing, unauthorized modification or misuse, operation outside of the environmental specifications for the product, or improper site preparation or maintenance.

NO OTHER WARRANTY IS EXPRESSED OR IMPLIED. HP SPECIFICALLY DISCLAIMS THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

EXCLUSIVE REMEDIES

THE REMEDIES PROVIDED HEREIN ARE BUYER’S SOLE AND EXCLUSIVE REMEDIES. HP SHALL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, WHETHER BASED ON CONTRACT, TORT, OR ANY OTHER LEGAL THEORY.

ASSISTANCE

Product maintenance agreements and other customer assistance agreements are available for Hewlett-Packard products.

For any assistance, contact your nearest Hewlett-Packard Sales and Service Office. Addresses are provided at the back of this manual.
SAFETY CONSIDERATIONS

GENERAL
This product and related documentation must be reviewed for familiarization with safety markings and instructions before operation.

This product is a Safety Class I instrument (provided with a protective earth terminal).

BEFORE APPLYING POWER
Verify that the product is set to match the available line voltage and the correct fuse is installed.

SAFETY EARTH GROUND
An uninterruptible safety earth ground must be provided from the main power source to the product input wiring terminals, power cord, or supplied power cord set.

SAFETY SYMBOLS
⚠️ Instruction manual symbol: the product will be marked with this symbol when it is necessary for the user to refer to the instruction manual (refer to Table of Contents).
⚡ Indicates hazardous voltages.
┻┻ Indicates earth (ground) terminal.

WARNING
The WARNING sign denotes a hazard. It calls attention to a procedure, practice, or the like, which, if not correctly performed or adhered to, could result in personal injury. Do not proceed beyond a WARNING sign until the indicated conditions are fully understood and met.

CAUTION
The CAUTION sign denotes a hazard. It calls attention to an operating procedure, practice, or the like, which, if not correctly performed or adhered to, could result in damage to or destruction of part or all of the product. Do not proceed beyond a CAUTION sign until the indicated conditions are fully understood and met.

Any interruption of the protective (grounding) conductor (inside or outside the instrument) or disconnecting the protective earth terminal will cause a potential shock hazard that could result in personal injury. (Grounding one conductor of a two conductor outlet is not sufficient protection).

Whenever it is likely that the protection has been impaired, the instrument must be made inoperative and be secured against any unintended operation.

If this instrument is to be energized via an autotransformer (for voltage reduction) make sure the common terminal is connected to the earth terminal of the power source.

Servicing instructions are for use by service-trained personnel only. To avoid dangerous electric shock, do not perform any servicing unless qualified to do so.

Adjustments described in the manual are performed with power supplied to the instrument while protective covers are removed. Energy available at many points may, if contacted, result in personal injury.

Capacitors inside the instrument may still be charged even if the instrument has been disconnected from its source of supply.

For continued protection against fire hazard, replace the line fuse(s) only with 250V fuse(s) of the same current rating and type (for example, normal blow, time delay, etc.). Do not use repaired fuses or short circuit fuseholders.
ATTENTION
Static Sensitive Devices

This instrument was constructed in an ESD (electro-static discharge) protected environment. This is because most of the semiconductor devices used in this instrument are susceptible to damage by static discharge.

Depending on the magnitude of the charge, device substrates can be punctured or destroyed by contact or mere proximity of a static charge. The results can cause degradation of device performance, early failure, or immediate destruction.

These charges are generated in numerous ways such as simple contact, separation of materials, and normal motions of persons working with static sensitive devices.

When handling or servicing equipment containing static sensitive devices, adequate precautions must be taken to prevent device damage or destruction.

Only those who are thoroughly familiar with industry accepted techniques for handling static sensitive devices should attempt to service circuitry with these devices.

In all instances, measures must be taken to prevent static charge build-up on work surfaces and persons handling the devices.

For further information on ESD precautions, refer to "SPECIAL HANDLING CONSIDERATIONS FOR STATIC SENSITIVE DEVICES" in Section VIII Service Section.
Figure 1-1. HP 8901B Modulation Analyzer and Supplied Accessories
Section 1
GENERAL INFORMATION

1–1. INTRODUCTION TO THIS MANUAL

The HP 8901B Operating and Service Manual is comprised of an Operation and Calibration Manual and the three volume Service Manual. These four volumes contain all the information required to install, operate, test, adjust, and service the Hewlett-Packard Model 8901B Modulation Analyzer.

The information to operate and service this instrument is made available as follows: Sections 1 through 5 are contained in this Operation and Calibration Manual (that includes the Basic Operation and Application Guide) which is provided with each instrument. Sections 6 through 8 are contained in the Service Manual that is not included with the instrument but which can be obtained by mailing in the Service Manual Request Card included in this manual.

The Modulation Analyzer is shown in Figure 1–1 with all supplied accessories. These manuals document Modulation Analyzers supplied with Options 001, 002, 003, 004, and series 030.

Operation and Calibration Manual

Section 1, General Information describes the instruments documented by this manual and covers instrument description, options, accessories, specifications and other basic information. This section also contains instrument theory of operation on a simplified block diagram level.

Section 2, Installation provides information about initial inspection, preparation for use (including address selection for remote operation), and storage and shipment.

Section 3, Operation provides information about panel features and includes operating checks, and operating instructions for both local and remote operation.

Section 4, Performance Tests provides the information required to check performance of the instrument against the critical specifications in Table 1–1.

Section 5, Adjustments provides the information required to properly adjust the instrument.

Service Manual

Section 6, Replaceable Parts provides ordering information for all replaceable parts and assemblies.

Section 7, Instrument Changes provides backdating information, and retrofitting and modification information.

Section 8, Service provides the information required to repair the instrument.

Additional copies of the Operation and Calibration Manual or the Service Manual can be ordered separately through your nearest Hewlett-Packard office. The part numbers are listed on the title page of this manual.
1-2. SPECIFICATIONS

Instrument specifications are listed in Table 1-1. These are the performance standards, or limits, against which the instrument may be tested. Information listed in this table as Supplemental Characteristics, are not warranted specifications but are typical characteristics included as additional information for the user.

1-3. SAFETY CONSIDERATIONS

This product is a Safety Class I instrument (that is, provided with a protective earth terminal). The Modulation Analyzer and all related documentation must be reviewed for familiarization with safety markings and instructions before operation. Refer to the Safety Considerations page found at the beginning of this manual for a summary of the safety information.

Safety information pertinent to the task at hand (installation, operation, performance testing, adjustment or service) is found throughout these manuals.

1-4. RECOMMENDED TEST EQUIPMENT

Table 1-2 lists the test equipment and accessories recommended for use in testing, adjusting, and servicing the Modulation Analyzer. If any of the recommended equipment is unavailable, instruments with equivalent minimum specifications may be substituted. Table 1-2 also includes some alternate equipment listings. Table 1-3 lists a number of accessories required in addition to those contained in the Service Accessory Kit, HP 08901-60287.

1-5. INSTRUMENTS COVERED BY THIS MANUAL

Options

Electrical options 001, 002, 003, 004, series 030, and various mechanical options are documented in these manuals. The differences are noted under paragraph 1-8, Options, in Table 6-3, Replaceable Parts, and in the schematic diagrams in Section 8.

Serial Numbers

Attached to the instrument is a serial number plate. The serial number is in the form 1234A00123. The first four digits and the letter are the serial prefix. The last five digits form the sequential suffix that is unique to each instrument. The contents of these manuals apply directly to instruments having the same serial number prefix(es) as listed under SERIAL NUMBERS on the respective manual title pages.

For information concerning a serial number prefix not listed on the title page or in the Manual Changes supplement, contact your nearest Hewlett-Packard office.

1-6. DOCUMENTATION UPDATING

An instrument manufactured after the printing of these manuals may have a serial number prefix that is not listed on the manual title page. Having a serial number prefix that is greater than that shown on the title page indicates that the instrument is slightly different from those documented in the manual. In this case, your manual is provided with updating information to make it as current as possible. This updating information includes any hardware or software changes that have occurred as well as corrections to the documentation.

A Description of the Manual Update Packet

A Manual Update packet consists of replacement and addition pages which should be incorporated in your manual to bring it up to date.
Signing Up for the Documentation Update Service

Hewlett-Packard offers a Documentation Update Service that will provide you with further updates and changes as they become available. If you have not received update information that matches the serial number of your instrument, you can receive this information through the Update Service.

If you operate or service instruments with different serial prefixes, we strongly recommend that you join this service immediately to ensure that your manual is kept current. For more information, refer to the Documentation Update Service reply card included in this manual or contact:

Hewlett-Packard Company
Technical Writing Department
24001 E. Mission—TAF C-34
Spokane, WA 99220
(509) 922-4001

Also, if you join the update service, you can indicate whether you choose to be contacted in the future about the quality of the documentation you receive. We are trying to improve the documentation we provide and periodically survey customers as to their expectations of the manuals.

1-7. HEWLETT-PACKARD INTERFACE BUS (HP-IB)

Compatibility

The Modulation Analyzer’s capabilities are defined by the following interface functions: SH1, AH1, T5, TE0, L3, LE0, SR1, RL1, PP0, DC1, DT1, C0. The Modulation Analyzer interfaces with the bus via open-collector TTL circuitry. An explanation of the compatibility code may be found in IEEE Standard 488-1978, *IEEE Standard and Digital Interface for Programmable Instrumentation* or the identical ANSI Standard MC1.1.

For more detailed information relating to programmable control of the Modulation Analyzer, refer to *Remote Operation, Hewlett-Packard Interface Bus* in Section 3 of this *Operating Information* manual.

Selecting the HP-IB Address

The HP-IB address switches are located within the Modulation Analyzer. The switches represent a five-bit binary number. This number represents the talk and listen address characters which the controller must generate. In addition, two more switches allow the Modulation Analyzer to be set to talk only or to listen only. A table in Section 2 shows all HP-IB talk and listen addresses. Refer to *HP-IB Address Selection* in Section 2 of this *Operation and Calibration* manual.

1-8. ADDITIONAL EQUIPMENT INFORMATION

Options

Options are variations on the standard instrument which can be ordered during the purchase. The following list defines all currently available options. Refer to *Electrical Equipment Available* in this section for retrofit part numbers that can be ordered after the purchase.

**Option 001.** This option provides rear-panel (instead of front-panel) connections for RF INPUT, SENSOR input, MODULATION OUTPUT/AUDIO INPUT, and AM/FM and RF POWER CALIBRATION OUTPUTs.

**Option 002.** This option provides a high-stability \((1 \times 10^{-9}/\text{day})\) internal reference oscillator in place of the standard reference oscillator. In addition, a 10 MHz time base output is provided on the rear panel.
Option 003. This option provides both an output for the internal local oscillator signal and an input for an external local oscillator signal. Both connections are located on the rear panel. (This output is provided automatically with option 030 series instruments.)

Option 004. This option allows operation at line frequencies ranging from 48 to 400 Hz. Operation at frequencies greater than 66 Hz is restricted to less than 128.5 Vac line input.

Option 030. The High Selectivity Measurement option provides the capability to measure single-sideband carrier noise (AM or phase) quickly and accurately up to 1.3 GHz with an external LO. (An output for the internal local oscillator and an input for an external local oscillator signal is provided with these options.) This option is ordered with one of the following filter options:

Option 032. This option provides a 12.5 kHz adjacent channel filter.

Option 033. This option provides a 25 kHz adjacent channel filter.

Option 035. This option provides a 30 kHz (Cellular Radio) alternate channel filter.

Option 037. This option provides a carrier noise filter.

Options 907-909. These options are described in Mechanical Equipment Available.

Option 910. This option provides an extra copy of both the Operation and Calibration Manual and the Service Manual.

Accessories Supplied

The Accessories Supplied are pieces of equipment which are shipped automatically with every Modulation Analyzer.

Line Power Cable. The line power cable may be supplied in several plug configurations, depending on the destination of the original shipment. Refer to Power Cables in Section 2 of this Operating Information manual.

Fuses. Fuses with a 2.5A rating for 115 Vac (HP 2110-0083) and a 1.5A rating for 230 Vac (HP 2110-0043) are supplied. One fuse is factory installed according to the voltage available in the country of original destination. Refer to Line Voltage and Fuse Selection in Section 2 of this Operating Information manual.

Electrical Equipment Available

This equipment is available to be ordered for the Modulation Analyzer after the time of sale.

HP-IB Controller. The Modulation Analyzer has an HP-IB interface and can be used with any HP-IB compatible computing controller or computer for automatic systems applications.

Sensor Module. The HP 11722A and 11792A Sensor Modules enable you to characterize a signal using a single input connector. Switching back and forth between the Modulation Analyzer's SENSOR input and RF INPUT connectors happens automatically with these modules (which contain an internal switch). The HP 11722A covers the frequency range 100 kHz to 2.6 GHz; the HP 11792A covers the range 50 MHz to 26.5 GHz and is intended for use with the HP 11793A Down Converter. Special care is taken with each sensor module to minimize input SWR and resulting errors. A low SWR attenuator isolates the power sensor from the source-under-test, reducing mismatch. Microwave hardware and a selected RF input cable further improve SWR and insertion loss.
Down Converter. The HP 11733A Down Converter, when used with a suitable local oscillator, extends the useful range of the Modulation Analyzer into the microwave region. Provisions have been made in the Modulation Analyzer to account for the frequency of the local oscillator and provide direct display of the frequency of the microwave input signal.

Test Source. The HP 11715A AM/FM Test Source produces extremely linear AM and FM at high rates as well as a low-noise CW signal. This source is required for performance testing and adjusting the Modulation Analyzer; however, it is an excellent stand-alone instrument for generating very low-distortion FM in the broadcast band.

Service Accessory Kit. A Service Accessory Kit (HP 08901-60287) is available which contains accessories (such as extender boards and cables) useful in servicing the Modulation Analyzer.

Front-to-Rear-Panel Connectors Retrofit Kit (Option 001). This kit contains all the necessary components and full instructions for converting front-panel connections to rear-panel connections. Order HP part number 08901-60282.

Rear-to-Front-Panel Connectors Retrofit Kit (Standard). This kit contains all the necessary components and full instructions for converting Option 001 instruments with rear-panel connections to instruments with front-panel connections. Order HP part number 08901-60283.

High-Stability, Internal-Reference Retrofit Kit (Option 002). This kit contains all the necessary components and full instructions for installation of the high-stability, internal-reference oscillator. Order HP part number 08901-60281.

Rear-Panel Local Oscillator Connections Retrofit Kit (Option 003). This kit contains all the necessary components and full instructions for installation of rear-panel local oscillator connections. Order HP part number 08901-60280. (These connections are already included in all Option 030 Series instruments.)

Conversion to 400 Hz Line Operation. Modulation Analyzers not equipped to operate at line power frequencies greater than 66 Hz may be converted to operate at line frequencies from 48 to 440 Hz. However, operation at line frequencies greater than 66 Hz will be restricted to line voltages less than or equal to 126.5 Vac. To convert to 400 Hz operation, order HP part number 08901-60095. After installation, performance will be identical to the HP 8901B Option 004.

Mechanical Equipment Available

The following kits might have been ordered and received with the Modulation Analyzer as options. If they were not ordered with the original shipment and are now desired, they can be ordered from the nearest Hewlett-Packard office using the appropriate part number.

Front-Handle Kit (Option 907). Ease of handling is increased with the front-panel handles. Order HP part number 5061-9690 for the basic kit and 2190-0048 for lockwashers (8 required).

Rack-Flange Kit (Option 908). The Modulation Analyzer can be solidly mounted to the instrument rack using the flange kit. Order HP part number 5061-9678.

Rack-Flange and Front-Handle Combination Kit (Option 909). This is not a front-handle kit and a rack-flange kit packaged together; it is composed of a unique part which combines both functions. Order HP part number 5061-9684 for the basic kit and 2190-9609 for lockwashers (8 required).
**Chassis Slide-Mount Kit.** This kit is extremely useful when the Modulation Analyzer is rack mounted. Access to internal circuits and components or the rear panel is possible without removing the instrument from the rack. Order HP part number 1494-0017 for 432 mm (17 in.) fixed slides. (To order adapters for non-HP rack enclosures, use HP part number 1494-0023.)

**Chassis-Tilt, Slide-Mount Kit.** This kit is the same as the Chassis Slide Mount Kit above except it also allows the tilting of the instrument up or down 90°. Order HP part number 1494-0025 for 432 mm (17 in.) tilting slides. To order adapters for non-HP rack enclosures, use HP part number 1494-0023.

1–9. DESCRIPTION OF THE MODULATION ANALYZER

The HP Model 8901B Modulation Analyzer is a complete measurement system for accurately characterizing signals in the 150 kHz to 1300 MHz frequency range. It combines the capabilities of four separate instruments in its ability to measure RF power, carrier frequency, modulation and the characteristics of the demodulated audio signal (as well as those of external audio signals). This flexibility allows you to make those measurements most commonly needed to totally characterize a signal.

The Modulation Analyzer can measure an RF signal’s frequency, frequency drift, power level (broadband, and off-channel), amplitude modulation (AM), frequency modulation (FM), phase modulation (FM), and AM and FM noise components. It recovers the modulating signal and can measure the audio signal’s frequency and distortion.

The Modulation Analyzer is fully automatic and all major measurements can be made by pushing a single key. The Modulation Analyzer’s large digital display shows measurement results with excellent resolution and is easy to read. All Modulation Analyzer operations can be controlled and all measurement results can be transferred via the Hewlett-Packard Interface Bus (HP-IB). (HP-IB is Hewlett-Packard’s implementation of IEEE Standard 488 and ANSI Standard MC1.1.)

**RF Power Measurements**

The Modulation Analyzer delivers the accuracy and resolution of a high-performance power meter. The HP 8901B, with the HP 11722A Sensor Module, measures power from +30 dBm to −20 dBm at frequencies from 100 kHz to 2.6 GHz. (Refer to Table 1–1, Specifications, for specified frequencies limits using other power sensors. The HP 8901B also accepts all HP 8480 series power sensors for extended measurement capability.)

**Input Power Protection.** The Modulation Analyzer is equipped with input power protection to prevent damage from the accidental application of excessive power. (This is a common cause of damage in equipment used to measure transmitters.) The Modulation Analyzer is tested for inputs up to 2W. Protection is provided by limiting diodes and an RF relay. When excessive power is applied, the relay opens and protects sensitive components, and the Modulation Analyzer displays an error message. The circuit automatically resets whenever a key is depressed.

**RF Power Calibration.** RF Power Calibration is accomplished with the 50 MHz, 1 mW standard available in every instrument. Also, the front-panel ZERO function enables you to zero the sensor module without removing it from the source-under-test. After the ZERO key is pressed, the new zero offsets are stored automatically.

**RF Power Calibration Factors.** RF Power Calibration Factors can be entered from the power sensor into the Modulation Analyzer’s non-volatile memory. The instrument automatically compensates for the power sensor’s efficiency and mismatch loss at each frequency.
High Selectivity Measurements. Options 030-037 add selective power measurement capability to the HP 8901B Modulation Analyzer. Used with a low-noise external LO, the HP 8901B performs fast, accurate single-sideband (SSB) carrier noise measurements to 1.4 GHz.

RF Frequency Measurements
In automatic operation, the Modulation Analyzer has the performance of a high-quality, 150 kHz to 1300 MHz frequency counter. The frequency counter automatically adjusts itself as the input level changes. There is no need to manually set or adjust the input attenuator. Because the Modulation Analyzer is usually used to measure modulated signals, its frequency counter also accurately measures signals with significant levels of AM.

Modulation Measurements
The Modulation Analyzer has extremely low internal noise. Incidental AM, FM, and ΦM can be measured on a wide range of simple and complex modulated signals. To complement its modulation measurement capability, the HP 8901B characterizes audio signal level, frequency, and distortion. (These features are also available for external audio signals.)

Filters, De-emphasis Networks and Modulation Calibrators
Post-Detection Audio Filters. The Modulation Analyzer has two high-pass and three low-pass post-detection audio filters for filtering the recovered modulation. These filters can be selected individually or in combination. Their cutoff frequencies have been chosen to match those needed for applications such as transmitter or signal generator testing. The >20 kHz filter is a Bessel filter. It minimizes overshoot for square-wave modulation so that this type of modulating waveform can also be accurately measured.

De-Emphasis Networks. The Modulation Analyzer contains four de-emphasis networks that can be used in addition to the audio filters. These are the ones commonly used in FM communications—25, 50, 75, and 750 μs. When selected, the de-emphasis networks always affect the demodulated output. You can select whether the de-emphasis network affects the deviation measured. The ability to select either the actual or "de-emphasized deviation" increases the usefulness of the Modulation Analyzer in many applications.

Modulation Calibrators. One of the most difficult problems involved in making very accurate measurements of AM depth or FM deviation is generating a precisely modulated signal to use as a calibration standard. In all instruments, a precise AM and FM modulation standard is included.

When the output of the calibrator is connected to the Modulation Analyzer's input, the amount of modulation is measured to create a calibration factor. The calibration factor can be used to automatically compensate all subsequent measurements. The calibration factor is the ratio of the measured modulation to the internally-computed modulation of the calibrator, expressed in %.

Additional Features
Tuning Features. In automatic operation, the Modulation Analyzer automatically tunes to the input signal and measures it.

In manual operation, you can determine the frequency to which the Modulation Analyzer tunes. Entering the approximate frequency on the keyboard causes all but very close interfering signals to be eliminated. This allows the Modulation Analyzer to selectively measure signals other than the largest.

A track mode feature enables you to track a signal, as it changes frequency, from either automatic or manual tune operation.
Store and Recall functions. These functions enable you to store eight complete instrument settings in non-volatile memory and recall them as needed.

Display Flexibility. The Modulation Analyzer offers numerous data-display formats. For example, RF power can be displayed in watts, dBm, V, dBV, mV, dBmV, μV, and dBμV. Use the RATIO and LOG/LIN keys to display results in dB or % relative to either a measured value or a value entered from the keyboard. These features eliminate the need for recalculating measurement results.

Special Functions

The Modulation Analyzer can do more than is apparent from the front panel. Many functions are accessed using the numeric keys and a Special Function key. The Special Functions provide access to other measurements and functions, manual control of instrument functions, instrument operation verification, and service aids.

All instrument functions not set using these Special Functions remain in the automatic mode. This allows you to select any combination of manual or automatic operations. By depressing the special key alone, the display shows ten digits that indicate which functions are in automatic and the state of those manually set.

There are also numerous Special Functions that can be used in verifying that the instrument and its various sections are operating properly. These, along with service special functions, make diagnosing and repairing the Modulation Analyzer faster and easier.

Those Special Functions that are most commonly used in operating the Modulation Analyzer are described on the Special Function Information pull-out card under the front panel.

Extending Measurement Range

Operation to 42 GHz is accomplished when an external LO and mixer are included in the measurement path. This system then functions as a single instrument making microwave modulation, frequency, power, and level measurements. You control operation from the Modulation Analyzer’s front panel. When the external LO frequency must be changed, the Modulation Analyzer requests an external controller to make the change. A separate, non-volatile calibration factor table is available in Frequency Offset mode for your microwave power sensor.

Programmability

The Modulation Analyzer is completely programmable via the Hewlett-Packard Interface Bus (HP-IB). This, coupled with the diversity of measurements the Modulation Analyzer can make, the speed with which these measurements can be made, and the flexibility of the Special Functions, make the instrument ideal for systems applications. In many instances it can reduce the number of instruments in a system, speed measurements, reduce complexity and improve accuracy.

When the Modulation Analyzer is in remote, the front-panel annunciators make it very easy to determine the state the instrument is in; whether it is in the talk, listen, or service request state.

1-10. PRINCIPLES OF OPERATION USING A SIMPLIFIED BLOCK DIAGRAM

The Modulation Analyzer is a calibrated, superheterodyne receiver, which converts the incoming signal to a fixed, intermediate frequency (IF), which is then demodulated. As in a radio receiver, the Modulation Analyzer contains an RF amplifier, a local oscillator (LO), a mixer, an IF amplifier and bandpass filter, a demodulator (detector or discriminator), and audio filters (tone controls). The Modulation Analyzer, however, contains additional features which make it much more versatile:

• automatic tuning,
• selectable measurement mode: signal frequency, power level, or modulation (AM, FM, or Phase Modulation (PM)),
• selectable audio detector (peak, average, or rms responding),
• audio counter,
• audio distortion analyzer,
• measurement calibrators (AM, FM, or power level), and
• HP-IB programmability.

The entire operation of the instrument is governed by a microprocessor-based Controller. The Controller sets up the instrument at turnon, interprets keyboard entries, executes changes in internal hardware, and displays measurement results and error messages. The computing capability of the Controller is also used to simplify circuit operation. For example, it forms the last stage of the Counter, calculates the AM or FM generated by the AM and FM Calibrators, and converts measurement results into ratios (in % or dB). The Controller also contains routines useful for servicing the instrument.

RF Circuitry

The RF input signal normally enters an external Sensor Module such as an HP 11722A. (See Figure 1–2.) For all measurements except RF Power, the Sensor Module routes the signal to the RF input connector of the Modulation Analyzer. For the RF Power measurement, the input signal passes directly into the Power Sensor, which converts the RF power absorbed by the RF Power Sensor into a low-frequency, chopped, ac voltage whose amplitude is proportional to the average RF power. The Power Meter amplifies the chopped signal and converts it to a dc voltage which is then measured by the voltmeter. (The voltmeter includes the Audio Peak Detector, Audio Average Detector, Voltage-to-Time Converter, and Counter.) The calibration of the Power Meter can be verified by connecting the Sensor Module to the CALIBRATION RF POWER OUTPUT connector on the front panel. (The 50 MHz Power Reference Oscillator is an accurate 1 mW reference.)

**CAUTION**

The Power Sensor is unprotected against and is easily damaged by sudden, large overloads. Refer to Table 1–1 under RF Power, Supplemental Characteristics, RF Power Ranges of HP 8901B Modulation Analyzer with HP 11722A Sensor Module, for information on maximum operating levels.

When the RF Peak Detector senses that the input signal level exceeds 1W, it opens the Overpower Relay. This is done without intervention of the Controller. The output from the RF Peak Detector, read by the voltmeter, is used to set the Input Attenuator to optimize the level applied to the Input Mixer.

The Input Mixer converts the input signal to the intermediate frequency (IF). For frequencies greater than 10 MHz, the IF is 1.5 MHz with the Local Oscillator (LO) tuned 1.5 MHz above the input frequency; an IF of 455 kHz can be manually selected for this frequency range. The 455 kHz IF is selected automatically for input signals between 2.5 MHz and 10 MHz. Below 2.5 MHz, the input passes directly through the Input Mixer without down-conversion.

**NOTE**

For the input signal to pass through the Input Mixer without down-conversion, the LO must still be present to turn the mixer diodes on. An LO frequency of 101.5 MHz is arbitrarily used. Thus the instrument will respond to input frequencies of 100 or 103 MHz as well as frequencies between 150 kHz and 2.5 MHz.

The instrument can be manually tuned to a desired signal even in the presence of larger signals, although filtering may be necessary since low-frequency signals pass directly into the IF. The RF High-Pass Filter can be inserted (via a Special Function) in the RF path for this purpose.

To measure the input frequency, the Counter measures the frequency of the LO and the frequency of the IF from the output of the IF Amplifier and Filter. The Controller computes and displays the difference between the two frequencies. For input frequencies below 2.5 MHz, only the IF is counted, which equals the input frequency.
Figure 1-2. HP 8901B Modulation Analyzer Simplified Block Diagram
LO Circuitry

The LO drives the high-level port of the Input Mixer and is one of several inputs to the Counter. The LO has four main modes of operation:

- tuning to the frequency required to down-convert a signal whose frequency is entered from the keyboard (manual tune mode),
- automatically searching for an input signal, then tuning the LO to the frequency required to down-convert the signal (automatic tune mode),
- automatically searching for an input signal, then configuring the LO in a feedback loop that automatically tracks the signal (automatic tune track mode), and
- tuning to the frequency required to down-convert a signal whose frequency is entered from the keyboard, then configuring the LO in a feedback loop that automatically tracks the input signal (manual tune track mode).

The manual tune track mode is useful when it is desired to follow an unstable signal in the presence of other signals. The non-track modes are used when the LO noise (residual FM) must be minimized.

IF Circuitry

The gain of the IF Amplifier is fixed. The IF Filters determine the frequency response of the IF. When the 1.5 MHz IF is selected, the IF filter consists of a 150 kHz to 2.5 MHz bandpass filter (with a nominal center frequency of 1.5 MHz). When the 455 kHz IF is selected, the IF filter is the Wide 455 kHz Bandpass Filter (with a bandwidth of 200 kHz).

In instruments with Option Series 030, the IF signal is further processed by the Channel Filters (which also include a precision, variable-gain amplifier) and detected by the IF RMS Detector. The Channel Filters set the IF bandwidth and gain for the Selective Power measurement. The measurement is made by entering a series of Special Functions which establish an IF reference in the center of the Channel Filter, then allow the relative IF level to be displayed as the IF frequency is detuned by a pre-determined offset.

Audio Circuitry

The modulation on the IF is demodulated by either the AM or the FM Demodulator. Phase modulation is recovered by integrating the demodulated FM in the Audio Filters and Gain Control circuitry.

The demodulated signal is amplified and filtered in the Audio Filters and Gain Control circuitry. The filters are selected from the front panel, and for FM, the filtering may also include de-emphasis. The processed signal is passed to the front-panel MODULATION OUTPUT/AUDIO INPUT connector and the voltmeter.

The audio signal from the Audio Filters and Gain Control is converted to a dc voltage by the Audio Peak Detector, the Audio Average Detector or the Audio RMS detector. The Audio Average and RMS Detectors are used primarily for measuring noise. The output from the detectors is routed into the Voltage-to-Time Converter.

The Voltage-to-Time Converter within the voltmeter converts the dc input into a time interval. During the interval, the 10 MHz Time Base Reference is counted by the Counter, and the resultant count represents the dc voltage. Other inputs to the voltmeter, which are not shown, include outputs from an audio level detector and the AM calibrator.

The Distortion Analyzer measures the distortion of either the internal demodulated signal or an audio signal applied externally to the MODULATION OUTPUT/AUDIO INPUT connector. The frequency of the input signal must be either 1 kHz or 400 Hz. The distortion on the signal is determined by measuring the amplitude of the signal before and after a notch filter that is set to 1 kHz or 400 Hz. The two ac signals are converted to dc by a the Audio RMS Detector and then measured by the voltmeter. Distortion is computed as the ratio of the voltage out of the notch filter to the voltage into the filter. (The Audio RMS Detector can also be used to measure the demodulated AM, FM, or 6M internally or the ac level of an external audio signal applied to the MODULATION OUTPUT/AUDIO INPUT connector.)
The frequency of the audio signal at the MODULATION OUTPUT/AUDIO INPUT connector, whether internal or external, is measured by a reciprocal-type Audio Counter. In the Audio Counter, the input signal is used to gate the 10 MHz Time Base Reference into the main Counter. (This gating function is also used by the Voltage-to-Time Converter.) The number of time base pulses received during the count is read by the Controller which computes and displays the signal frequency.

The AM and FM Calibrators provide a nominal 10.1 MHz signal with a precisely known amount of AM or FM. When this signal is applied to the instrument’s RF INPUT connector (either directly or via the Sensor Module), the modulation is measured and the calibration factor of the AM or FM Demodulator is computed and displayed. Related front-panel functions are automatically set for proper demodulation of the calibrator signal.

![Figure 1-3. A Baseband Signal and the Corresponding Amplitude Modulated Carrier](image)

1-11. MODULATION BASICS

The Modulation Analyzer can demodulate and measure three types of modulation: amplitude modulation (AM), frequency modulation (FM), and phase modulation (PM). In general, modulation is that characteristic of a signal which conveys the information. A signal without modulation is said to be a continuous-wave (CW) signal. CW signals contain two information-carrying parameters: amplitude and frequency. These two parameters, however, are static (time invariant). Consequently, the information conveyed by them is scant—you know only that a signal is present at a certain frequency. When one or both of these parameters is altered as a function of time, the signal is said to be modulated.

The RF signal which is modulated is called the carrier. The modulating signal is referred to as the baseband signal and can be of any arbitrary form (for example, voice, tone, noise). Demodulation is the process of recovering the baseband signal from the modulated carrier. The Modulation Analyzer can measure the modulation on carriers in the range of 150 kHz to 1300 MHz. Measurement accuracy is specified for modulation rates generally between 20 Hz and 100 kHz. The demodulated signal is present at the MODULATION OUTPUT connector.

Amplitude Modulation

As the name implies, a carrier is amplitude modulated when its amplitude is varied as a function of time. Figure 1-3 shows a carrier with amplitude modulation and, for reference, also shows the baseband signal. As you can see, the tips of the carrier trace out a waveform that resembles the baseband signal. This trace is called the envelope. The envelope rises to a maximum called the peak and drops to a minimum called the trough. A quantity which describes the amount of AM or the AM depth is the
modulation index. If the peak amplitude is called $P$ and the trough amplitude is called $T$, the modulation index $m$ (usually expressed in %) is defined as

$$m = \frac{P - T}{P + T} \times 100\%.$$ 

In the example of Figure 1-3, $P = 1.5$ and $T = 0.5$; therefore,

$$m = \frac{1.5 - 0.5}{1.5 + 0.5} \times 100\% = 50\%.$$ 

Figure 1-4 shows AM signals with modulation indexes varying from 0 to 100%.

Figure 1-4. AM for Various Depths
When the baseband signal is symmetrical, the modulation index can also be expressed in terms of the average carrier level, $A$, and the envelope peak, $r$, relative to the carrier. Then $P = A + r$, and $T = A - r$, and the expression for modulation index becomes

$$m = \frac{A + r - A + r}{A + r + A - r} \times 100\% = \frac{2r}{2A} \times 100\% = \frac{r}{A} \times 100\%.$$ 

This is the expression which the Modulation Analyzer evaluates when making an AM measurement. Referring back to Figure 1–3, it is apparent that $A = 1$ and $r = 0.5$ so, as before

$$m = \frac{0.5}{1} \times 100\% = 50\%$$

The Modulation Analyzer makes an AM measurement by forcing the average carrier level, $A$, to a known, fixed level by means of an automatic level control (ALC) circuit. The signal is then demodulated, and the amplitude of the recovered baseband signal is measured with a peak detector. The output of the detector is $r$, which is (in effect) multiplied by the constant $100/A$ and displayed as the % AM.

Figure 1–5 illustrates an AM signal with an asymmetrical baseband source. The first definition of modulation index still applies here. For it, $m = 46\%$. The second definition, however, does not apply since $P - A \neq A - T$. The Modulation Analyzer detects a different value for $r$ if the positive peak of the recovered signal is detected than if the negative peak is detected. Thus a different modulation index is measured in PEAK+ than PEAK−.

![Figure 1–5. AM with an Asymmetrical Baseband Signal](image)

The range of modulation indexes for AM measurements by the Modulation Analyzer is essentially 0 to 100%. There are, however, types of modulation that produce modulation indexes greater than 100%. An example of such is suppressed-carrier AM. The Modulation Analyzer is not intended for measuring such signals. Nevertheless, there are cases, when the Modulation Analyzer will display a modulation index that exceeds 100%. This can occur, for example, on an asymmetrical waveform where a narrow peak is greater than the average carrier level. This is illustrated in Figure 1–6.
Exponential Modulation

Exponential (or angular) modulation is the generic name given to modulation in which the frequency or phase of the carrier is varied. Frequency and phase modulation are very closely related. In fact, it is impossible to tell whether the signal was produced by a frequency modulator or phase modulator by analyzing the received signal unless specific information about the baseband signal is given.

It is certainly true to say that a signal is frequency modulated when the modulation is generated by a frequency modulator. A varactor diode across the tank circuit of an LC oscillator will produce FM when the varactor bias is varied. It is also true that a signal is phase modulated when the modulation is generated by a phase modulator. A varactor diode across an RF filter will produce PM when the varactor bias is varied. (It is assumed that the carrier is on the slope of the filter and that the filter is driven from a well-buffered carrier source. This modulator simultaneously produces AM.)

The signal from both modulators will show readings on the Modulation Analyzer when in both the FM and PM measurement modes. When in FM, the quantity being measured is the peak frequency deviation, which is the maximum frequency excursion from the average carrier frequency. When measuring PM, the peak phase deviation is measured, which is the maximum phase excursion from the average carrier phase. Phase and frequency have the relationship that phase is the integral of the frequency or frequency is the derivative of the phase. In fact, the Modulation Analyzer demodulates PM by integrating the demodulated FM.

This relationship is most easily visualized by some examples. Look at Figure 1-7. The first baseband signal shown is a square wave. The three waveforms under it are the result of applying this signal to an FM, PM, and AM modulator respectively. (The AM waveform is included only for reference.) It is assumed that the phase modulator doesn’t produce AM—only PM. The FM waveform is as expected. The frequency goes up on the positive peak of the baseband signal and down on the negative peak. The phase modulated signal, however, is peculiar. The frequency is generally constant throughout except for a discontinuity where the baseband signal switches amplitude. The waveform of the figure was contrived so that a 180° phase shift occurred exactly at a zero crossing of the carrier. In general, a discontinuity will occur when the baseband signal switches amplitude, but the phase shift is not necessarily 180° and does not need to occur at a zero crossing of the carrier. Mathematically, the derivative of a square wave is the constant zero except for a positive spike (impulse) where the baseband signal switches positive and a negative spike where the square wave switches negative.

Now look at the triangle wave. The frequency modulator produces a continually increasing frequency as the baseband signal slopes upward and a continually decreasing frequency as the signal slopes downward. The phase modulator produces a signal that resembles the signal from the frequency modulator for the square wave baseband signal. This is because the derivative of a constant slope is a constant. When the slope is positive, the phase shift is continually increasing, thus producing a uniform frequency shift upward. When the slope is negative, the phase shift is continually decreasing and produces a downward frequency shift. For the triangle wave baseband signal, the shift in frequency when the slope changes is proportional to the change in slope.
Figure 1-7. Signals from Frequency, Phase, and Amplitude Modulators

Now note the sine wave of Figure 1-7(c). The signals from the frequency and phase modulators look the same except for the 90° phase shift between the two. For the frequency modulated signal, the frequency is highest when the baseband signal is most positive and lowest when most negative. For the phase modulated signal, the frequency is highest when the slope of the baseband signal is steepest in a positive direction. This occurs at the positive-going zero crossing. Similarly, the frequency is lowest when the slope is most negative.

If in the last example, the rate, but not the amplitude, of the baseband signal is increased, the highest and lowest frequencies of the signal from the frequency modulator stay the same—they just occur more often. However, for the signal from the phase modulator, not only do the frequency peaks occur more often, but the excursions are large because the slopes of the baseband signal are steeper at the zero crossings. See Figure 1-7(d).

The maximum frequency deviation which can be measured is 400 kHz. The maximum phase deviation is 400 rad or 400 kHz divided by the modulation rate, whichever is smaller. As with AM, an asymmetrical baseband waveform will result in different readings in PEAK+ than PEAK−.
Other Considerations

In practice, it is difficult to produce an FM or $\Phi M$ signal which does not also have a small amount of AM—called incidental AM or AM-on-FM. Likewise, an AM signal usually contains a small amount of incidental FM and $\Phi M$. In order to accurately measure this incidental modulation, the Modulation Analyzer itself must not contribute to it. This contribution is specified as AM rejection and FM rejection.

A typical CW signal also contains a small amount of residual AM, FM, and $\Phi M$. The residual modulation is generated by such things as line hum, noise, and microphonics. The residual AM and FM specifications quantify the residual modulation internal to the Modulation Analyzer.

Residual modulation affects the modulation readings in a manner which depends on the detector used, the nature of the residuals, and the signal-to-noise ratio. If the residual is predominately noise, when the peak detector is used, the residuals add in a way that is statistically related to the signal-to-noise ratio. This is discussed under Residual Noise Effects in the Detailed Operating Instructions in Section 3. When the average detector is used, the residuals add approximately in an rms manner, that is, the square root of the sum of the squares of the noise and the signal. The effect of this noise becomes insignificant, however, when the signal-to-noise ratio rises above a few dB. Noise can be further reduced by filtering the demodulated signal.
In FM broadcasting and communications, the signal-to-noise ratio is improved by giving the baseband signal a high-frequency boost before applying it to the modulator. This is called pre-emphasis. The boost is a simple 6 dB per octave with the 3 dB corner specified by a time constant; for example, 75 μs (which corresponds to a 3 dB corner of 2.12 kHz) for commercial broadcast FM. If desired, the demodulated FM can be de-emphasized to equalize the signal at the modulation output and at the display.
Table 1–1. Specifications (1 of 6)

| ZERO DRIFT OF SENSORS (1 HOUR, AT CONSTANT TEMPERATURE AFTER 24-HOUR WARM-UP): |
| ±0.1% of full scale of lowest range for 11722A Sensor Module and 8481A/1B/1H/2A/2B/2H/3A/5A Sensors. |
| ±2.0% of full scale of lowest range for 8484A Sensor. Decrease by a factor of 10 for each higher range. |

| RF POWER RANGES OF 8901B MODULATION ANALYZER WITH 11722A SENSOR MODULE: |
| −20 dBm to −10 dBm (10 μW to 100 μW), range 1. |
| −10 dBm to +0 dBm (100 μW to 1 mW), range 2. |
| +0 dBm to +10 dBm (1 mW to 10 mW), range 3. |
| +10 dBm to +20 dBm (10 mW to 100 mW), range 4. |
| +20 dBm to +30 dBm (100 mW to 1 W), range 5. |

| RESPONSE TIME (0 to 99% OF READING): |
| <10 seconds, range 1. |
| <1 second, range 2. |
| <100 milliseconds, ranges 3-5. |

| DISPLAYED UNITS: |
| Watts, dBm, dB_{relative}, %_{relative}, Volts, μV, dB V, dB mV, dB μV. |

| INTERNAL NON-VOLATILE CAL-FACTOR TABLES (user-modifiable using special functions): |
| MAXIMUM NUMBER OF CAL FACTOR/FREQUENCY ENTRIES: |
| Table #1 (Primary): 16 pairs plus Reference Cal Factor. |
| Table #2 (Frequency Offset): 22 pairs plus Reference Cal Factor. |

| MAXIMUM ALLOWED FREQUENCY ENTRY: |
| 200 GHz. |

| FREQUENCY ENTRY RESOLUTION: |
| 50 kHz. |

| CAL FACTOR RANGE: |
| 40 to 120%. |

| CAL FACTOR RESOLUTION: |
| ±0.1%. |

**Power Reference**

| POWER OUTPUT: |
| 1.00 mW. Factory set to ±0.7%, traceable to the U.S. National Bureau of Standards. |

| ACCURACY: |
| ±1.2% worst case (±0.9% rss) for one year (0°C to 55°C). |

**Supplemental Characteristics:**

| FREQUENCY: |
| 50 MHz nominal. |

| SWR: |
| 1.05 nominal. |

| FRONT PANEL CONNECTOR: |
| Type-N female. |

---

1 The 8901B fundamental RF Power measurement units are watts. Further internal processing is done on this number to display all other units.

2 When using 8484A sensor the noise specification may mask the linearity specification and become the predominant error. When operating on the top RF power range, add the Power Sensor Linearity percentages found in the power sensor specifications.

---

All parameters describe performance in automatic operation or properly set manual conditions. **Specifications** describe the instrument’s warranted performance. **Supplemental Characteristics** (shown in italics) are intended to provide information useful in applying the instrument by giving typical, but non-warranted, performance parameters.
Amplitude Modulation

</tr>
<tr>
<td>0.001% (rms detector only)</td>
<td>0.1 V/percent</td>
<td>AM rms &lt; 3%</td>
</tr>
</tbody>
</table>

3 But not to exceed: 50 Hz to 40 kHz rates for stated accuracy with rms detector.
4 Peak residuals must be accounted for in peak readings.
5 For peak measurements only; AM accuracy may be affected by distortion generated by the Analyzer. In the worst case this distortion can decrease accuracy by 0.1% of reading for each 0.1% of distortion.
6 Flatness is the variation in indicated AM depth for constant depth on input signal.
7 For optimum flatness, cables should be terminated with their characteristic impedance.

---

**Frequency Modulation**

**RATES:**
- 20 Hz to 10 kHz, 150 kHz ≤ f_s < 10 MHz.
- 20 Hz to 200 kHz, 10 MHz ≤ f_s < 1300 MHz.

**DEVIATIONS:**
- 40 kHz peak maximum, 150 kHz ≤ f_s < 10 MHz.
- 400 kHz peak maximum, 10 MHz ≤ f_s < 1300 MHz.

**ACCURACY:**

<table>
<thead>
<tr>

</tbody>
</table>

Resolution is increased one digit with 750 μs de-emphasis and pre-display on.

The demodulated output signal present at the Modulation Out/Audio In connector is increased in amplitude by a factor of 10 with 750 μs de-emphasis.

6 But not to exceed: 20 kHz rates and 40 kHz peak deviations with 750 μs de-emphasis filter.
7 With 750 μs de-emphasis and pre-display "off" distortion is not specified for modulation output ≥4V peak. This condition can occur near maximum deviation for a measurement range, at rates ≤2 kHz.

DETECTORS: +peak, −peak, ±peak/2, peak hold, average (rms sinewave calibrated), rms.

STEREO SEPARATION (50 Hz to 15 kHz): >47 dB.

Phase Modulation

RATES: 200 Hz to 10 kHz, 150 kHz ≤ f_s < 10 MHz, 200 Hz to 20 kHz, 10 MHz ≤ f_s ≤ 1300 MHz.

ACCURACY:
+4% of reading ±1 digit, 150 kHz ≤ f_s < 10 MHz,
+3% of reading ±1 digit, 10 MHz ≤ f_s ≤ 1300 MHz.
For rms detector add ±3% of reading.

DEMODULATED OUTPUT DISTORTION: <0.1% THD.

AM REJECTION (FOR 50% AM AT 1 kHz RATES):
<0.03 radians peak (50 Hz to 3 kHz BW).

MAXIMUM DEVIATION, RESOLUTION, AND MAXIMUM DEMODULATED OUTPUT SENSITIVITY ACROSS AN OPEN CIRCUIT (600Ω OUTPUT IMPEDANCE):

Supplemental Characteristics:

MODULATION RATES: usable from 20 Hz to 100 kHz with degraded performance.

DETECTORS: +peak, −peak, ±peak/2, peak hold, average (rms sinewave calibrated), rms.

Modulation Reference

AM CALIBRATOR DEPTH AND ACCURACY:
33.33% depth nominal, internally calibrated to an accuracy of ±0.1%.

FM CALIBRATOR DEVIATION AND ACCURACY:
34 kHz peak deviation nominal, internally calibrated to an accuracy of ±0.1%.

Supplemental Characteristics:

CARRIER FREQUENCY: 10.1 MHz.
MODULATION RATE: 10 kHz.
OUTPUT LEVEL: −25 dBm.

Frequency Counter

RANGE: 150 kHz to 1300 MHz.
MAXIMUM RESOLUTION: 1 Hz.

ACCURACY:
± reference accuracy ±3 counts of least-significant digit, f_s < 100 MHz.
± reference accuracy ±3 counts of least-significant digit or 50 Hz, whichever is larger, f_s ≥ 100 MHz.

Supplemental Characteristics:

MODES:
Frequency and Frequency Error (displays the difference between the frequency entered via the keyboard and the actual RF input frequency).

SENSITIVITY IN MANUAL TUNING MODE:
0.22 mV rms (~60 dBm). (Approximate frequency must be entered from keyboard.)

Internal Reference

FREQUENCY: 10 MHz.

AGING RATE:
<1 × 10⁻⁶/month, <1 × 10⁻⁸/day (Option 002).

Supplemental Characteristics:

INTERNAL REFERENCE ACCURACY:
Overall accuracy is a function of time base calibration ± aging rate ± temperature effects ± line voltage effects ± short-term stability.

</table>

**Supplemental Characteristics:**

- **DISPLAYED RESOLUTION:** 6 digits.
- **MEASUREMENT RATE:** 2 readings/s.
- **COUNTING TECHNIQUE:** Reciprocal with internal 10 MHz time base.
- **AUDIO INPUT IMPEDANCE:** 100 kΩ nominal.

**Audio Distortion**

**FUNDAMENTAL FREQUENCIES:**
400 Hz ± 5% and 1 kHz ± 5%.

**MAXIMUM EXTERNAL INPUT VOLTAGE:** 3V.

**DISPLAY RANCE:**
0.01% to 100.0% (-60.00 dB to 0.00 dB).

**DISPLAYED RESOLUTION:**
0.01% or 0.01 dB.

**ACCURACY:** ±1 dB of reading.

**SENSITIVITY:**
- Modulation: 0.15 kHz peak FM, 1.5% peak AM or 0.6 radian peak φM.
- External: 100 $mV_{\text{rms}}$.

**RESIDUAL NOISE AND DISTORTION:**
0.3% (~50 dB), temperature ≤40°C.

**Supplemental Characteristics:**

- **MEASUREMENT 3 dB BANDWIDTH:** 20 Hz to 50 kHz.
- **DETECTION:** True rms.
- **MEASUREMENT RATE:** 1 reading/s.
- **AUDIO INPUT IMPEDANCE:** 100 kΩ nominal.

Audio RMS Level

**FREQUENCY RANGE:** 50 Hz to 40 kHz.

**VOLTAGE RANGE:** 100 mV to 3V.

**ACCURACY:** ± 4.0% of reading.

**Supplemental Characteristics:**

- **FULL RANGE DISPLAY:** 3000V, 4000V.
- **AC CONVERTER:** true-rms responding for signals with crest factor of ≤3.
- **MEASUREMENT RATE:** 2 readings/s.
- **AUDIO INPUT IMPEDANCE:** 100 kΩ nominal.

**Audio Filters**

**DE-EMPHASIS FILTERS:** 25 μs, 50 μs, 75 μs, and 750 μs. De-emphasis filters are single-pole, low-pass filters with 3 dB frequencies of 8966 Hz for 25 μs, 3193 Hz for 50 μs, 2122 Hz for 75 μs, and 212 Hz for 750 μs.

- **50 Hz HIGH-PASS FILTER (2 POLE):** Flatness: <1% at rates ≥ 200 Hz.
- **300 Hz HIGH-PASS FILTER (2 POLE):** Flatness: <1% at rates ≥ 1 kHz.
- **3 kHz LOW-PASS FILTER (5 POLE):** Flatness: <1% at rates ≥ 1 kHz.
- **15 kHz LOW-PASS FILTER (5 POLE):** Flatness: <1% at rates ≥ 10 kHz.
- **>20 kHz LOW-PASS FILTER (9 POLE BESSEL):** Flatness: <1% at rates ≥ 10 kHz.

**Supplemental Characteristics:**

- **DE-EMPHASIS FILTER TIME CONSTANT ACCURACY:** ±3%.
- **HIGH PASS AND LOW PASS FILTER 3 dB FREQUENCY ACCURACY:** ±3%.
- **>20 kHz LOW PASS FILTER:** 3 dB Cutoff Frequency: 100 kHz nominal.
- **OVERSHOOT ON SQUARE WAVE MODULATION:** <1%.

---

12 With the low-pass and high-pass audio filters used to stabilize frequency readings.
13 For demodulated signals, the residual noise generated by the 8901B must be accounted for in distortion measurements (i.e., residual AM, FM or φM)
14 The >20 kHz low-pass filter is intended for minimum overshoot with squarewave modulation.
Table 1–1. Specifications (5 of 6)

### RF Input

**FREQUENCY RANGE:** 150 kHz to 1300 MHz.

**OPERATING LEVEL:**

<table>
<thead>
<tr>
<th>Minimum Operating Level</th>
<th>Maximum Operating Level</th>
<th>Frequency Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>12 mV&lt;sub&gt;rms&lt;/sub&gt; (−25 dBm)</td>

<td>650 MHz–1300 MHz</td>
</tr>
</tbody>
</table>

### Supplemental Characteristics:

**TUNING:**
- **Normal Mode:** Automatic and manual frequency entry.
- **Track Mode:** Automatic and manual frequency entry, \( f_c > 10 \text{ MHz} \).
- **Acquisition Time (automatic operation):** ~1.5 seconds.

**INPUT IMPEDANCE:** 500 nominal.

**MAXIMUM SAFE DC INPUT LEVEL:** 5V.

### General Specifications

**TEMPERATURE:** Operating: 0°C to 55°C.

**REMOTE OPERATION:** HP-IB; all functions except the line switch are remotely controllable.

**HP-IB COMPATIBILITY (defined in IEEE 488-1978):**
- SH1, AH1, T5, TE0, L3, LEO, SR1, RL1, PP0, DC1, DT1, C0, E1.

**EMI:** Conducted and radiated interference is within the requirements of VDE 0871 (Level B) and CISPR publication 11.

**POWER:** 100, 120, 220, or 240V (+5%, −10%); 48–66 Hz; 200 VA maximum.

**WEIGHT:** Net 23.4 kg (51.5 lb); Shipping 31.1 kg (68.5 lb).

**DIMENSIONS:** 190 mm. H × 426 mm, W × 551 mm. D (7.5" × 16.8" × 21.7").

**HP SYSTEM II MODULE SIZE:** 177.0 H × 1 MW × 497.8 D.

### HP 8901B Rear Panel Inputs/Outputs

**Supplemental Characteristics:**

**FM OUTPUT:** 10 kΩ impedance, −9V to 6V into an open circuit, −6V/MHz, dc coupled, 16 kHz bandwidth (one pole).

**AM OUTPUT:** 10 kΩ impedance, −4V to 0V into an open circuit, −8 mV/%, dc coupled, 16 kHz bandwidth (one pole).

**RECORDER OUTPUT:** DC voltage proportional to the measured results, 1 kΩ impedance, 0V to 4V for each resolution range into an open circuit.

**IF OUTPUT:** 50Ω impedance, 150 kHz to 2.5 MHz, −27 dBm to −3 dBm.

**10 MHz REFERENCE OUTPUT:** 50Ω impedance, TTL levels (0V to >2.2V into an open circuit). Available only with Option 002 1×10⁻⁸/day internal reference.

**10 MHz REFERENCE INPUT<sup>15</sup>** >500Ω impedance, 0.5V<sub>peak-to-peak</sub> minimum input level.

**LO INPUT (Option 003):** 50Ω impedance, ~1.27 MHz to 1301.5 MHz, 0 dBm nominal.

**RF SWITCH REMOTE CONTROL OUTPUT:** Provides output signals necessary to remotely control either an HP 33311B/C Option 011 or an HP 8761A RF switch.

**FREQUENCY OFFSET MODE REMOTE CONTROL OUTPUT:** TTL high output if in frequency offset mode (Special Function 27.1 or 27.3) with an external LO frequency >0, TTL low output for all other cases.

---

<sup>15</sup>External reference accuracy affects accuracy of all measurements.
Carrier Noise (Options 030–037)

FREQUENCY RANGE: 10 MHz to 1300 MHz.

CARRIER POWER RANGE: +30 dBm to −20 dBm;
12.5 kHz, 25 kHz and 30 kHz filters.
+30 dBm to −10 dBm; carrier noise filter.

DYNAMIC RANGE: 115 dB.

CARRIER REJECTION (temp. ≤35°C) >90 dB; for offsets of
at least 1 channel spacing or 5 kHz, whichever is greater.

RELATIVE MEASUREMENT ACCURACY: ±0.5 dB;
levels ≥−95 dBc; 12.5 kHz, 25 kHz and 30 kHz filters:
±0.5 dB; levels ≥−129 dBc/Hz; carrier noise filter.

CARRIER NOISE FILTER:
Filter Noise Bandwidth: 2.5 kHz nominal.

Noise Bandwidth Correction Accuracy (stored in
non-volatile memory): ±0.2 dB.

Supplemental Characteristics:

ADJACENT/ALTERNATE CHANNEL FILTERS:
6 dB Filter Bandwidth:
8.5 kHz, 12.5 kHz adjacent-channel filter.
16.0 kHz, 25 kHz adjacent-channel filter.
30.0 kHz, 30 kHz (cellular radio) alternate-
channel filter.

TYPICAL NOISE FLOOR: −150 dBc/Hz, 0 dBm carrier
power level. For System noise performance add LO
contribution.

Section 2
INSTALLATION

2-1. INTRODUCTION TO THIS SECTION

This section provides the information needed to install the Modulation Analyzer. Included is information pertinent to initial inspection, power requirements, line voltage selection, power cables, interconnection, operating environment, instrument mounting, storage and shipment. This section also contains a procedure for setting the internal HP-IB talk and listen address switches and a procedure for removing the pull-out cards.

2-2. INITIAL INSPECTION

WARNING

To avoid hazardous electrical shock, do not perform electrical tests when there are signs of shipping damage to any portion of the outer enclosure (covers, panels, meters).

Inspect the shipping container for damage. If the shipping container or cushioning material is damaged, it should be kept until the contents of the shipment have been checked for completeness and the instrument has been checked mechanically and electrically. Procedures for checking electrical performance are given in Section 4. If the contents are incomplete, if there is mechanical damage or defect, or if the instrument does not pass the electrical performance test, notify the nearest Hewlett-Packard office. If the shipping container is damaged, or the cushioning material shows signs of stress, notify the carrier as well as the Hewlett-Packard office. Keep the shipping materials for the carrier's inspection.

2-3. PREPARATION FOR USE

Power Requirements

WARNING

To avoid the possibility of hazardous electrical shock, do not operate this instrument at line voltages greater than 126.5 Vac with line frequencies greater than 66 Hz. Leakage currents at these line settings may exceed 3.5 mA.

The Modulation Analyzer requires a power source (+5% to −10%) of 100, 120, 220, or 240 Vac, 48 to 66 Hz single phase. Option 004 also operates from 48 to 440 Hz single phase, 120 Vac, (+5% to −10% only). Power consumption is 200 VA maximum.
WARNING

This is a Safety Class I product (that is, provided with a protective earth terminal). An uninterruptible safety earth ground must be provided from the main power source to the product input wiring terminals, power cord, or supplied power cord set. Whenever it is likely that the protection has been impaired, the product must be made inoperative and be secured against any unintended operation.

If this instrument is to be energized via an external autotransformer, make sure the autotransformer’s common terminal is connected to the earthed pole of the power source.

Power Cables

WARNING

BEFORE CONNECTING THIS INSTRUMENT, the protective earth terminals of this instrument must be connected to the protective conductor of the (Mains) power cord. The Mains plug shall only be inserted in a socket outlet provided with a protective earth contact. The protective action must not be negated by the use of an extension cord (power cable) without a protective conductor (grounding).

This instrument is equipped with a three-wire power cable. When connected to an appropriate ac power receptacle, this cable grounds the instrument cabinet. The type of power cable plug shipped with each instrument depends on the country of destination. Refer to Table 2-1 for the part numbers of the power cables available.

* Part number shown for plug is industry identifier for plug only. Number shown for cable is HP Part Number for complete cable including plug. E = Earth; Ground; L = Line; N = Neutral; STR = Straight.
Line Voltage and Fuse Selection

CAUTION

BEFORE PLUGGING THIS INSTRUMENT into the Mains (line) voltage, be sure the correct voltage and fuse have been selected.

Verify that the line voltage selection card and the fuse are matched to the power source. Refer to Figure 2–1, Line Voltage and Fuse Selection.

Fuses may be ordered under HP part numbers 2110-0083, 2.5A (250V normal blow) for 115 Vac operation and 2110-0043, 1.5A (250V normal blow) for 230 Vac operation.

Selection of Operating Voltage and Fuse Replacement

1. Open cover door, pull the FUSE PULL lever and rotate to left. Remove the fuse.
2. Remove the Line Voltage Selection Card. Position the card so the line voltage appears at top-left corner. Push the card firmly into the slot.
3. Rotate the FUSE PULL lever to its normal position. Insert a fuse of the correct value in the holder. Close the cover door.

Figure 2–1. Line Voltage and Fuse Selection

HP-IB Address Selection

The HP-IB address switches are located within the Modulation Analyzer. The switches represent a five-bit binary number. This number represents the talk and listen address characters which an HP-IB controller must generate. In addition, two more switches allow the Modulation Analyzer to be set to talk only or to listen only.
WARNING

Setting of the HP-IB address should be performed only by service trained persons who are aware of the potential shock hazard of working on an instrument with protective covers removed.

To avoid hazardous electrical shock, the line (Mains) power cable should be disconnected before attempting to change the HP-IB address.

In the Modulation Analyzer, the HP-IB talk and listen addresses are selectable by an internal switch (Figure 2–2). This address can be read by selecting BUS ADRS (Blue Key, LOCAL). The following procedure explains setting of the switches. Refer to Table 2–2 for a listing of the talk and listen addresses. In the factory, the address is set for a talk address of “N” and a listen address of “.” (period). In binary, this is 01110; in decimal it is 14.

1. Disconnect the line (Mains) power cable.
2. Remove any HP-IB cables or connectors from the HP-IB connector.
3. Remove the Modulation Analyzer’s top cover.
   a. Remove the two plastic feet from the rear of the top cover by removing the pan-head Pozidriv screw within each foot.
   b. Unscrew the Pozidriv screw at the center of the rear edge of the top cover. This is a captive screw and will cause the top cover to pull away from the front frame.
   c. Lift off the top cover.
4. Locate the HP-IB address switch on the A14 Remote Interface Assembly near the front right of the instrument. The A14 assembly may be recognized as having one brown and one yellow printed circuit board extractor.

Figure 2–2. The HP-IB Address Switch Shown as Set by the Factory
The Address Shown is 01110 in Binary (14 in Decimal) With Both Talk Only and Listen Only Off
5. Use a pencil to set the switches to the desired HP-IB address and Talk Only (TON) or Listen Only (LON) condition. The switch is illustrated in Figure 2-2. Facing the board, the left hand switch (marked with a "5") is the most significant address bit (A5 in Table 2-2). Setting a switch toward the printed circuit board places it in its “1” position. If the TON and LON switches are both set to “1”, the Talk Only setting will override. If the address switches and the TON switch are all set to “1”, the Modulation Analyzer will output one byte (the status byte) each measurement cycle. (Setting all switches to “1” defeats HP-IB operation.)

6. Reinstall the top cover by reversing the procedure in previous step 3.

7. Connect the line (Mains) power cable to the Line Power Module and reconnect the HP-IB cable to the HP-IB connector.

8. To confirm the address, turn on the instrument and select BUS ADRS (Blue Key, LOCAL). To confirm a talk only or listen only setting, key in 21.0 SPCL. The display shows a binary number in the form AAAAA.TLS where AAAAA is the HP-IB address in binary and T,L, and S indicate talk, listen, and service request status.

Logic Levels
The Hewlett-Packard Interface Bus logic levels are TTL compatible, that is, the true (1) state is 0.0 Vdc to +0.4 Vdc and the false (0) state is 2.5 Vdc to +5 Vdc.

Programming and Output Data Format
Refer to Section 3 "Operation".

Mating Connector
HP 1251-0293; Amphenol 57-30240

Mating Cables Available
HP 10833A, 1 meter (3.3 ft.), HP 10833B 2 meters (6.6 ft.)
HP 10833C 4 meters (13.2 ft.), HP 10833D, 0.5 meters (1.6 ft.)

Cabling Restrictions
1. A Hewlett-Packard Interface Bus system may contain no more than 2 meters (6.6 ft.) of connecting cable per instrument.
2. The maximum accumulative length of connecting cable for any Hewlett-Packard Interface Bus system is 20 meters (65.6 ft.).

Figure 2–3. Hewlett-Packard Interface Bus Connection
Interconnections

Interconnection data for the Hewlett-Packard Interface Bus is provided in Figure 2-3.

Mating Connectors

**Interface Connector.** The HP-IB mating connector is shown in Figure 2-3. Note that two securing screws are metric.

**Coaxial Connectors.** Coaxial mating connectors used with the Modulation Analyzer should be the 50Ω BNC male connectors or 50Ω Type-N male connectors that are compatible with those specified in US MIL-C-39012.

The application note, “Principles of Microwave Connector Care” (HP part number 5958-7442) can help you improve measurements and reliability. Suggestions in the application note will help you get the best performance from all microwave connectors. It will show what to look for when cleaning and inspecting connectors (in order to preserve their precision and extend their life) and how to make the best possible microwave connections (improving the accuracy and repeatability of all your measurements).

Operating Environment

The operating environment should be within the following limitations:

- Temperature: $-0^\circ C$ to $+55^\circ C$
- Humidity: $<95\%$ relative
- Altitude: 4570 meters (15 000 feet)

Bench Mounting

The instrument cabinet has plastic feet and fold-away tilt stands for convenience in bench operation. (The plastic feet are shaped to ensure self-aligning of the instruments when stacked.) The tilt stands raise the front of the instrument for easier viewing of the front panel.

Rack Mounting

**WARNING**

_The Modulation Analyzer is heavy for its size (23.6 kg, 52 lb). Care must be exercised when lifting to avoid personal injury. Use equipment slides when rack mounting._

Rack mounting information is provided with the rack mounting kits. If the kits were not ordered with the instrument as options, they may be ordered through the nearest Hewlett-Packard office. (Refer to paragraph 1-8, Additional Equipment Information under Mechanical Equipment Available. Before rack mounting the Modulation Analyzer, the Operating Information pull-out tray (attached to the bottom of the instrument) must first be removed. To remove the pull-out card assembly, refer to the procedure that follows.

Removal and Installation of Operating Information Pull-Out Cards

**Steps for Removal.** Follow the procedure below to remove the Operating Information pull-out card assembly:

1. Remove the two front feet of the instrument.
2. Remove the Operating Information tray assembly by sliding the tray toward the rear of the instrument and then down.
3. Remove the information cards by bowing them slightly in the middle and pulling it straight up (away from the tray).
**Steps for Installation.** Follow the procedure below to reinstall the *Operating Information* pull-out card assembly:

1. Install the information card by bowing it slightly in the middle and carefully guiding the edges into the plastic guide slots near the front of the tray.
2. Push the information card all the way into the tray.
3. Place the information tray assembly between the rear feet of the instrument and slide it forward until the tabs are locked under the rear feet.
4. Replace the front feet of the instrument.

**2–4. STORAGE AND SHIPMENT**

**Environment**

The instrument should be stored in a clean, dry environment. The following environmental limitations apply to both storage and shipment:

- **Temperature**: \(-55^{\circ}C\) to \(+75^{\circ}C\)
- **Humidity**: \(<95\% \text{ relative}
- **Altitude**: \(15 \text{ 300 meters (50 000 feet)}\)

**Packaging**

**Original Packaging.** Containers and materials identical to those used in factory packaging are available through Hewlett-Packard offices. If the instrument is being returned to Hewlett-Packard for servicing, attach a tag indicating the type of service required, return address, model number and full serial number. Also mark the container FRAGILE to assure careful handling. In any correspondence refer to the instrument by model number and full serial number.

**Other Packaging.** The following general instructions should be used for re-packaging with commercially available materials:

1. Wrap the instrument in heavy paper or plastic. (If shipping to a Hewlett-Packard office or service center, attach a tag indicating the service required, return address, model number and full serial number.)
2. Use a strong shipping container. A double-wall carton made of 1.9 MPa (275 psi) test material is adequate.
3. Use enough shock-absorbing material (75 to 100 mm layer; 3 to 4 in.) around all sides of instrument to provide firm cushion and prevent movement in the container. Protect the front panel with cardboard.
4. Seal the shipping container securely.
5. Mark the shipping container FRAGILE to assure careful handling.
Section 3
OPERATION

3–1. INTRODUCTION TO THIS SECTION

This section provides advanced operating information for the Modulation Analyzer. Included in this section are descriptions of all front and rear-panel controls, connectors, and indicators, remote and local operator’s checks, operating instructions, and operator’s maintenance.

Local Operation Section

Information regarding front-panel operation of the Modulation Analyzer is provided in the sections described in the following paragraphs. To most rapidly learn the basic operation of the instrument, refer to the separate Basic Operation and Application Guide and/or perform the Operator’s Checks. Once familiar with the general operation of the instrument, use the Detailed Operating Instructions for the most in-depth and complete information on operating the Modulation Analyzer.

Remote Operation Section

The Modulation Analyzer is capable of remote operation via the Hewlett-Packard Interface Bus (HP-IB). Provided in this section are instructions pertinent to HP-IB operation including all specific considerations and instructions (including capabilities, address formats, input and output formats, the status byte, and service requests). At the end of the discussion is a complete summary of all codes and formats.

HP-IB information concerning remote information also appears in several other locations. Address setting is discussed in Section 2, a summary of HP-IB codes and output formats appears on the Operating Information pull-out card, and a list of relevant program codes for each function appears in the Detailed Operating Instructions. (Detailed Operating Instructions are described above in the paragraph, Local Operation Section.)

Basic Functional Checks Section.

Basic Functional Checks are simple procedures designed to be performed by the operator. These checks verify the proper operation of the Modulation Analyzer’s main functions and HP-IB capabilities. These checks can also be used to familiarize the first-time operator with basic Modulation Analyzer measurements and HP-IB capabilities. Two procedures are provided:

Basic Functional Checks of the Modulation Analyzer. This procedure assures that most front-panel controlled functions are being properly executed by the Modulation Analyzer. The checks require the use of a sensor module, a signal generator, an oscilloscope, and interconnecting cables and adapters.

Basic Functional Checks of the Hewlett-Packard Interface Bus (HP-IB)

This series of procedures requires only an HP-IB compatible computing controller and an HP-IB interface and connecting cable. The HP-IB Functional Checks assume that front-panel operation has been verified (for example, by performing the Basic Functional Checks).
Detailed Operating Instructions Section

The Detailed Operating Instructions provide a complete operating reference for the Modulation Analyzer user. The instructions are organized into tabbed sections oriented toward specific measurement types. Besides information on the various measurements, the instructions contain individual discussions of nearly all controls, inputs, and outputs. Also included are instructions for using the many user special functions. A guide to using the Detailed Operating Instructions is provided ahead of the instructions themselves.

Other Sources of Operating Information

Pull-Out Cards. The Operating Information and Special Function Information Pull-Out Cards are flexible plastic reference sheets attached to the Modulation Analyzer by a tray located beneath the front panel. They contain a brief summary of front-panel operation and displays. Also included on the cards is a complete listing of HP-IB codes, data, and error output formats, error codes, and user special functions. The cards show a simplified block diagram for the Modulation Analyzer and provide basic instructions for RF Power and AM and FM Measurements. The pull-out cards are intended to be a reference for the user who already has a basic understanding of front-panel operation.

Supplemental Information. Other information, pertinent to operating the Modulation Analyzer to its fullest capabilities, are contained in Section 1. “Principles of Operation for a Simplified Block Diagram” (in paragraph 1–10) is a fundamental description of what the Modulation Analyzer is and how it works. This information supplements the block diagrams provided on the pull-out card and in the Detailed Operating Instructions. “Modulation Basics” (in paragraph 1–11) is a discussion about the way the Modulation Analyzer makes modulation measurements. All of this information helps to provide a basis for applying the Modulation Analyzer to various measurement situations.

3–2. OPERATING CHARACTERISTICS OF THE MEASURING RECEIVER

The major operating characteristics of the Modulation Analyzer are provided in paragraph 1–6, Description, and Table 1–1, Specifications. For information on HP-IB capabilities, refer to Remote section in this manual.

3–3. OPERATOR’S INFORMATION

Fuses

WARNING

For continued protection against fire hazard, replace the line fuse only with a 250V normal blow fuse of the same rating. Do not use repaired fuses or short-circuited fuseholders.

The only maintenance the operator should normally perform is the replacement of the primary power fuse located within the Line Power Assembly (A30). For instructions on how to change the fuse, refer to Figure 2–1, steps 1 and 3.

Fuses can be ordered using HP part number 2110–0083, 2.5A (250V, normal blow) for 100/120 Vac operation or 2110–0043, 1.5A (250V, normal blow) for 220/240 Vac operation.
Time Base 10 MHz Input and Time Base 10 MHz Output

WARNING

Do not apply greater than 20V peak (ac + dc) into the TIME BASE 10 MHz INPUT or damage to the instrument may result.

Do not apply greater than 3 Vdc or greater than +20 dBm into the TIME BASE 10 MHz OUTPUT or damage to the instrument may result.

Description

**Time Base 10 MHz Input.** Provides an input for an external 10 MHz time base reference. This input is ac coupled and requires an input signal level greater than 0.5 Vpp. The input impedance is approximately 500Ω.

The time-base circuitry of the Modulation Analyzer automatically switches to the external time base when an external time base of sufficient amplitude is applied.

When using an external time base reference, the accuracy of all measurements depends on the accuracy of the external reference. Frequency-related measurements are most noticeably affected by time-base inaccuracy.

To determine whether the Modulation Analyzer has actually switched in the externally applied time base, select 15.1 SPCL. If an external time base is being used, the display will show 1. If the internal time base is being used, the display will show 0.

If the Modulation Analyzer is using the internal, Option 002 time base, you can determine whether the time base oven is warm enough to create a stable source by selecting 15.0. The display will show a 0 if the time base oven is adequately warm. The display will show Error 12 if the time base is cold.

To drive several instruments from a single external reference, simply use a BNC tee at the Modulation Analyzer's TIME BASE 10 MHz INPUT.

If the internal time base fails, an external time base may still be used. Connect the external time base to TIME BASE 10 MHz INPUT, then switch the instrument's POWER switch to STBY and back to ON.

**Time Base 10 MHz Output.** (This output is available only with the high-stability reference, Option 002.) Provides an output for the internal 10 MHz reference. The output is a 500Ω, TTL compatible output (0V to greater than 2.2V into an open circuit).

When driven from an external reference, the Modulation Analyzer outputs the internal reference (not the external input signal). TIME BASE 10 MHz INPUT provides an input for an external 10 MHz time base reference. This input is ac coupled and requires an input signal level greater than 0.5 Vpp. The input impedance is approximately 500Ω.

3-4. TURN-ON PROCEDURE

**CAUTION**

Before the Modulation Analyzer is switched on, it must be set to the voltage of the power source, or damage to the instrument may result. Refer to paragraph 2-3, Power Requirements.

Do not apply greater than 40V (ac + dc) to the RF INPUT connector or damage to the instrument may result.
WARNING

Before the Modulation Analyzer is switched on, all protective earth terminals, extension cords, auto-transformers, and devices connected to it should be connected to a protective earth socket. Any interruption of the protective earth grounding will cause a potential shock hazard that could result in personal injury.

For continued protection against fire hazard, replace the line fuse with a 250V normal blow fuse of the same rating. Do not use repaired fuses or short-circuited fuseholders.

The Modulation Analyzer has a standby state and an on state. Whenever the power cable is plugged in, an internal power supply is activated. In instruments supplied with the high-stability reference (Option 002) the supply energizes the internal reference oven. If the Modulation Analyzer is already plugged in, set the POWER switch to ON. If the power cable is not plugged in, follow these instructions:

1. Check that the line voltage setting matches the power source. (See Figure 2–1, Line Voltage and Fuse Selection.)
2. Check that the fuse rating is appropriate for the line voltage used. (See Figure 2–1, Line Voltage and Fuse Selection.) Fuse ratings are provided in the paragraph Operator’s Maintenance in this section.
3. Plug in the power cable.
4. Set the POWER switch to ON.

NOTE

When the POWER switch is set to ON, all front-panel indicators light for approximately 10 seconds after which the instrument is ready to be operated.

3–5. INSTRUMENT FEATURES

Front-panel controls, indicators, and connectors are illustrated and referenced to text in Figure 3–1. The text for this figure describes the various functions of the Modulation Analyzer. At the end of each description is a reference to a detailed operating instruction that contains more details on this topic.

Rear-panel features are shown and referenced to text in Figure 3–2. The text for this figure provides a quick reference for rear-panel signal levels and frequencies and also includes the impedances at the rear-panel connections.

The information in parenthesis at the end of each feature summary provides the title of the Detailed Operating Instructions relevant to the feature.
Figure 3–1. Front-Panel Features
Front-Panel Features

The following list provides a brief description of each feature. The information in brackets provides the title of the Detailed Operating Instructions relevant to the feature. The index lists page numbers for the instructions.

1. MEASUREMENT keys enable the Modulation Analyzer to make and display the selected measurement. [See AM, FM, φM, RF Power, RF Input Frequency, Audio Frequency, Audio Distortion, IF Level, Tuned RF Level, RF Frequency Error.]

2. Numeric Display shows measurement results, error codes, or instrument or Special Function status.

3. Display Annunciators indicate the measurement result units. They also indicate that some measurement functions are enabled. All these annunciators are displayed when the Modulation Analyzer is first turned on.

4. AUTOMATIC OPERATION enables the Modulation Analyzer to automatically tune and to autorange to make the selected measurement. [See Automatic Operation.]

5. INSTR PRESET (Blue Key) configures the Modulation Analyzer to its power-up condition. [See Instrument Preset.]

6. TRACK MODE and AUTO TUNING (Blue Key) select the tuning mode of the Modulation Analyzer. [See RF Frequency Tuning.]

7. STORE (Blue Key) and RECALL (Blue Key) enable the Modulation Analyzer to store and recall up to eight measurement states. [See Store/Recall.]

8. WATTS, μV, mV, and VOLTS keys (all used with the Blue Key) enable selection of different units for level measurements.

9. MHz completes the keyboard entry of frequencies for various functions. This key is also used to complete the entry of frequencies used with RF Power calibration factors. [See RF Frequency Tuning, Frequency Offset Mode, RF Power.]

10. MODULATION OUTPUT/AUDIO INPUT connector provides either an output for the modulation recovered from the RF INPUT connector or an input for external audio signals to be processed by the audio circuitry. The MODULATION OUTPUT annunciators indicate the type of recovered modulation available as the output. The AUDIO INPUT key selects whether the internally demodulated signal or an external audio signal is to be processed by the Modulation Analyzer’s audio circuitry. [See Modulation Output/Audio Input, Audio Frequency, Audio Distortion and Level, SINAD.]

11. % CAL FACTOR (Blue Key) causes the Modulation Analyzer to display the current calibration factor for the selected measurement. This key is also used to complete the entry of calibration factors for various functions. [See AM Calibration, FM Calibration, RF Power.]

12. DISPLAY FREQ (Blue Key) causes the Modulation Analyzer to display the RF frequency that it tuned to last. [See Frequency Offset Mode, RF Power Calibration Factors.]

13. SENSOR connector provides the input for the power sensor. [See RF Power.]

14. kHz ↑ and kHz ↓ complete keyboard entry of frequency step-size (in kHz) for step tuning, or change the frequency in the increments specified. [See RF Frequency Tuning.]

15. DISPLAY FREQ INCR (Blue Key) causes the Modulation Analyzer to display the increment step-size. [See RF Frequency Tuning.]

16. INPUT couples the RF input signal into the instrument. [See RF Input Frequency.]

17. SPCL completes entry of Special Function codes that access additional instrument operations. Without a preceeding numeric entry, the SPCL key causes a display of the status of Special Functions 1 through 10. [See Special Functions.]
18. (–) (Blue Key) enables input data to be entered as a negative value.

19. RANGE HOLD freezes the current ranges being used by the Modulation Analyzer. [See Range Hold.]

20. Blue Key is a shift key that enables some keys to have two different functions. Any function printed in blue can be selected when the key associated with it is pressed after the Blue Key. (The Blue Key flashes at the current measurement rate whenever it is pressed.)

21. DISABLE ERROR (Blue Key) disables Error 01 through Error 04. [See Error Message Disable Control.]

22. LOG/LIN causes measurements to alternate between logarithmic and linear units. [See Ratio and Log/Lin.]

23. dB EXT ATTEN (Blue Key) enables level measurements to be offset with external attenuation or gain. [See External Attenuation.]

24. RATIO and PREVIOUS RATIO (Blue Key) cause the current measurement to be compared to a reference. [See Ratio and Log/Lin.]

25. Operating Information pull-out cards are quick operating references that list Special Function, HP-IB, and Error codes, show a simplified block diagram for the Modulation Analyzer, and provide basic information for RF Power and AM/FM Calibration.

26. DETECTOR keys select the audio detector used to measure the modulation. [See Audio Detectors, Audio Distortion and Level, SINAD.]

27. 1 kHz DISTN (Blue Key) and 400 Hz DISTN (Blue Key) enable the Modulation Analyzer to make audio measurements on either 1 kHz or 400 Hz audio signals. [See Audio Distortion and Level, SINAD.]

28. CALIBRATION AM/FM OUTPUT makes available a precisely modulated signal used to improve the Modulation Analyzer's AM or FM accuracy. [See AM Calibration, FM Calibration.]

29. CALIBRATE and SAVE CAL (Blue Key) enable the Modulation Analyzer to calibrate and save the resulting calibration factor for either RF Power, AM, or FM. The CALIBRATE key also initiates tuned RF level calibration operations. [See AM Calibration, FM Calibration, RF Power.]

30. CALIBRATION RF POWER OUTPUT makes available a 50 MHz, 1 mW power reference used to precisely determine the sensitivity of the external power sensor. [See RF Power.]

31. SET REF (Blue Key) is not a Modulation Analyzer function.

32. POWER switch applies power to the Modulation Analyzer when set to ON. [See Instrument Preset.]

33. ZERO causes the Modulation Analyzer to cancel any dc offset that may be present in the power sensor. [See RF Power.]

34. PRE DISPLAY enables FM deviation to be measured before or after de-emphasis. [See FM De-Emphasis.]

35. FM DE-EMPHASIS networks equalize pre-emphasized FM. [See FM De-Emphasis.]

36. HP (High-Pass) and LP (Low-Pass) FILTERS limit the demodulated signal bandwidth. [See Audio Filters.]

37. LOCAL returns the Modulation Analyzer to keyboard control from remote (HP-IB) control.

38. HP-IB Annunciators indicate remote operation status.
Figure 3-2. Rear-Panel Features
Rear-Panel Features

1. AM OUTPUT produces an ac signal, whose amplitude is proportional to the AM depth, with a dc component related to the IF level. The output is dc coupled with a 16 kHz bandwidth and a 10 kΩ output impedance. [See AM Output.]

2. FM OUTPUT produces an ac signal, whose amplitude is proportional to the FM deviation, with a dc component related to the IF frequency. The output is dc coupled with a 16 kHz bandwidth and a 10 kΩ output impedance. [See FM Output.]

3. RECORDER OUTPUT allows user-access to all internal measurement voltages. [See Recorder Output.]

4. IF OUTPUT produces a 150 kHz to 2.5 MHz modulated IF signal. The output level ranges from -27 to -3 dBm (50Ω output impedance). [See IF Output.]

5. TIME BASE 10 MHz OUTPUT and INPUT. The input connector provides an input for an external 10 MHz time base reference. The external input signal must be greater than 0.5V peak-to-peak (into a 500Ω input impedance). The output connector provides an output for the internal, high-stability 10 MHz reference. Output signal is TTL compatible (50Ω nominal output impedance). (Refer to paragraph 3-3. Time Base 10 MHz Input and Time Base 10 MHz Output.)

6. MODULATION OUTPUT/AUDIO INPUT is a rear-panel output and input supplied on Option 001 instruments. Refer to MODULATION OUTPUT/AUDIO INPUT referenced from Figure 3-1.

7. SENSOR is a rear-panel input for the power sensor supplied on Option 001 instruments. Refer to SENSOR referenced from Figure 3-1.

8. INPUT is a rear-panel input for the RF input signal. This input is supplied on Option 001 instruments. Refer to INPUT referenced from Figure 3-1.

9. Fuse. 2.5A (250V normal blow) for 100 or 120 Vac. 1.5A (250V normal blow) for 220 or 240 Vac.

10. Serial Number Plate. The first four numbers and letter comprise the prefix that denotes the instrument configuration. The last five digits form the suffix that is unique to each instrument.

11. Line Power Module permits operation from 100, 120, 220, or 240 Vac. The number visible in the window indicates the nominal line voltage to which the instrument must be connected. (See Figure 2-1, Line Voltage and Fuse Selection) The center conductor is safety earth ground.

12. FREQ OFFSET TTL OUT outputs a voltage that can be used to switch an external mixer in and out of the path between a microwave input signal and the Modulation Analyzer when the instrument is in Frequency Offset Mode. The TTL output is always 0V if Frequency Offset Mode is not selected or while Frequency Offset Mode is selected with an entered external LO value of 0 Hz. If the entered external LO frequency is less than or equal to 18 GHz, the TTL output is +5V. If the entered external LO frequency is greater than 18 GHz, the TTL output is 3V. (See Frequency Offset Control.)

13. HP-IB Connector connects the Modulation Analyzer to the Hewlett-Packard Interface Bus for remote operations. When the HP-IB is being used, the annunciators next to the LOCAL key light as appropriate (REMOTE, LISTEN, TALK, SRQ).

14. REMOTE CONTROL RF SWITCHES enable the user to build an internal sensor module that can switch between the RF INPUT connector and the SENSOR connector. [See Remote Control RF Switch.]

15. LO OUTPUT and INPUT (Option 003 and Option Series 030 only). Option 003 provides an LO output connector and an LO input connector. The LO output connector is provided to output the Local Oscillator signal. The output signal is 1.27 to 1301.5 MHz at approximately 0 dBm (50Ω) nominal output impedance. The LO input connector provides an input for an external Local Oscillator. External input signal required is 1.27 to 1301.5 MHz at approximately 0 dBm
(50Ω) nominal input impedance (LO Input and LO Output). Two jumpers are provided to allow the internal LO signal to be routed to the LO input connector when no external LO is in use.

The Option Series 030 instruments are provided with an LO input connector, an LO output connector and a remotely controllable switch which selects between them. If an external LO is connected but the signal is not in use, the switch routes the external LO signal back out the LO output connector. [See High Selectivity Measurements.]

**CAUTION**

Do not apply reverse power into the LO OUTPUT or damage to the instrument may result. Do not apply greater than 40 Vdc or +5 dBm of RF power into the LO INPUT or damage to the instrument may result.

16. CALIBRATION OUTPUT RF PWR and AM/FM produces a rear-panel output for RF Power and AM and FM calibrators. This output is supplied on Option 001 instruments instead of the standard front-panel connection. Refer to both CALIBRATION RF POWER OUTPUT and CALIBRATION AM/FM OUTPUT referenced from Figure 3–1.

3–6. REMOTE OPERATION VIA THE HEWLETT PACKARD INTERFACE BUS (HP-IB)

Introduction to the Section

This section documents how the instrument interacts with a controller over HP-IB in remote operation. This section is intended as a reference document for operators who are familiar with their controller protocol and programming language, and is designed to be used after you have been introduced to basic front-panel operation as shown in the Local section.

Accurate measurements are dependent on the proper functioning of both the HP-IB and the Modulation Analyzer. The Basic Functional Checks of the Modulation Analyzer and the Basic Functional Checks of the Hewlett - Packard Interface Bus (HP-IB) verify that the Modulation Analyzer and HP-IB are operating properly and can respond to or send bus messages.

How to Use this Section to Make a Measurement

Beginning Users: You will need to read the information presented in the Local section and perform the procedures described there to become familiar with the basic operation of the instrument. Then read the portions of the Detailed Operating Instructions (in this manual) describing the measurement you want to make. Then return to this section and read “Programming the Modulation Analyzer”, paragraph 3–7. This information should be enough to enable you to make most measurements.

Intermediate Users: If you are familiar enough with programming the instrument to feel you can skip the above steps, you may be interested in more specific information. In this case read the paragraphs titled, “Data Output”, “Hewlett Packard Interface Bus”, “Modulation Analyzer Remote Capabilities”, and/or “Additional Information” as appropriate to your needs.

Advanced Users: You may be able to program the instrument just using the tables in the back of this section which list the codes required to make measurements, the modifiers for each measurement, and other related information. Specific subjects such as Triggering, the Service Request Message and the Status Byte may be of interest. Explanations can be found in paragraphs of the same name.

3–7. PROGRAMMING THE MODULATION ANALYZER

Overview

All Modulation Analyzer functions are fully programmable, except the POWER switch.

The Modulation Analyzer can be externally triggered (Refer to “Triggering Measurements”, under paragraph 3–10.) Triggering can be used to allow the Modulation Analyzer to settle before making a measurement. It can be used to control when the Modulation Analyzer takes a measurement and outputs the result.

Valid Programming Codes

The HP 8901B will execute:

- The function codes described in Table 3–11, “Modulation Analyzer Function to Code Summary”.
- Valid special functions (refer to page 3–241 for a list of special functions). All special function codes are formed by the special function number followed by the code “SP”.
- The HP-IB commands described in Table 3–7, “Modulation Analyzer Remote Capabilities Table”.

As a convenience, all lower case alpha characters are treated as upper case. Commas and spaces between program codes are ignored by the instrument and therefore may be used to improve readability in programming.
Measurement Codes  All front-panel keys except the LOCAL key have corresponding instrument-dependent program codes. These codes consist of either two alphabetic characters, or an alphabetic character and a number; e.g., M3. The underlined letters on the front-panel key labels are both letters or the initial letter of the programming code for that function. For example, the code for AUTOMATIC OPERATION is AU, and the codes for TRACK MODE are K1 and K0. The entire list of programming codes required to make measurements with the HP 8901B (not including special functions) are contained in Tables 3-11 and 3-12.

Turning Off Functions  When operating in local operation, many of the functions toggle on and off with successive keystrokes. In remote operation, a specific code turns off the functions. The HP-IB Codes for turning off these functions are given in Table 3-1, “Turning Off Functions”.

Invalid Characters

The following Table 3-2, “Response to Unused ASCII Characters” lists the Modulation Analyzer’s response to various ASCII characters not used in its code set. The characters in the left-hand column are ignored unless they appear between two characters of a program code (e.g. M 3, space between the characters of a function code); in which case, they generate Error 24. The characters in the right-hand columns, if received by the Modulation Analyzer, will always cause Error 24 (invalid HP-IB code) and a Service Request message to be generated.

Programming Syntax

Function Code Syntax. The function code syntax is typically equivalent to the front-panel keystroke sequence used in local operation. (Refer to Basic Operation and Application Guide or the Detailed Operating Instructions for keystroke sequences.)

There are three different syntax which execute functions. Refer to Table 3–3, “Function Code Syntax Examples” for examples.

- Using a two character code or suffix alone, which is the common case.
- Using a number and a suffix.
- Using a prefix (usually a special function), a number and a suffix.

Table 3–3. Function Code Syntax Examples

</tbody>
</table>
**Numeric Data Syntax.** When entering input frequency, entering ratio or limit references, or entering any numeric data (other than two-character function codes) into the Modulation Analyzer, certain requirements must be met:

- Numeric data may consist of a signed mantissa of up to eight digits, with one decimal point, and a one- or two-digit, signed exponent.
- The decimal point may fall between any two digits of the mantissa. If a decimal point is entered before the first digit, a leading zero will be inserted by the Modulation Analyzer.
- Any digit beyond the eight allowed for the mantissa will be received as zero.

The following table shows examples of the differences between data entered into the Modulation Analyzer and the data accepted.

<table>

</tr>
</tbody>
</table>

**Code String Syntax (Sequence Dependency)**

For accurate measurement results, functions should be programmed in the following order to insure proper sequencing of events and switching in the instrument as appropriate to the measurement. The letter X in the following example represents a number.

Function codes that have the same alpha-character should be entered in numeric order to ensure proper execution; e.g., P1 should come before P4.

OUTPUT 714; AU XXX.XX MZ MX DX PX HXLX XX.XSP RX TX

The following information should be considered in addition to the information above when writing programming strings.

- **AU (Automatic Operation).** When Automatic Operation is used, it should appear at the beginning of a program string. Automatic Operation sets all special functions prefixed 1 through 10 to their zero-suffix mode. Most other special functions are also set to zero-suffix.
- **P0 (Pre-Display Off and De-Emphasis Off).** When pre-display is turned off using P0, all FM de-emphasis is turned off.
NOTE

Pre-Display is not turned off if the Audio RMS Detector (D8) is on when P0 is selected. In this case, FM De-emphasis will be turned off, but Pre-display will be left on. Pre-display is required by the Audio RMS hardware.

- T2 and T3 (Trigger Immediate and Trigger With Settling). Trigger codes should always appear at the end of a program string, and the triggered measurement results must be read before any additional program codes are sent to ensure an accurate measurement. When either of the trigger codes T2 or T3 is received by the Modulation Analyzer, a measurement cycle is immediately initiated.

Programming Examples

Code String Example. Function codes may be sent to the instrument in a continuous string as shown below. The code string shown will program the instrument to determine the positive peak de-emphasized (75 µs) FM deviation of an input signal at 104.5 MHz. The measurement is triggered with T3, Trigger with Settling.

OUTPUT 714," AUTOMATIC MODE, FM, PEAK- DETECTOR, AND FM DE-EMPHASIS

Example Measurement Program. The following example provides you with a sample of how the previous information might be used to program the HP 8901B to make a particular measurement. This example demonstrates measuring AM in the 50 Hz to 15 KHz bandwidth of a 100 MHz carrier using Trigger Hold and Trigger with Settling.

Reference Tables

Table 3-11, “Modulation Analyzer Function to Code Summary”. This table lists the instrument-specific function code for each Modulation Analyzer function described in the Detailed Operating Instructions of this manual.

Table 3-12, “Code to Modulation Analyzer Function Summary”. This table has the same information as Table 3-11, “Modulation Analyzer Function to Code” but is organized alpha-numerically by code.
NOTE
The following tables are intended as a reference for advanced users who are familiar with the HP 8901B measurement capabilities.

Table 3–14, “Measurement Modifiers”. Whenever a measurement is selected, the Modulation Analyzer sets up its internal circuitry so it can make the most accurate measurement possible. These settings can be altered by the operator to modify the measurement.

This table lists the measurement modifiers for the primary measurement modes listed in Table 3–13, “Measurement Modes and Codes”.

To see what modifiers are being automatically selected,
- use the Special Special display to read the Range in use,
- read the front-panel lights for the Detectors, Filters and De-Emphasis in use and
- see Table 3–15 or -16, “Enabling/Disabling Variable Parameters (Front Panel or Remote)” for a summary of how to read the Calibration Factors, the Frequency Offset, the dB external Attenuation, the Limits set, and whether Ratio has been selected.

Table 3–15, “Enabling/Disabling Variable Parameters (Front Panel)”. This table lists ways of verifying from the front panel the values of the Calibration Factors, Frequency Offset, dB External Attenuator, Limit/Ratio and Set Reference functions.

Table 3–16, “Enabling/Disabling Variable Parameters (Remote)”. This table is the same as Table 3–15 except that it shows the programming codes required instead of the front-panel keystrokes.

Table 3–17, “HP 8901A/02A Code Differences”. This table lists the function code differences for identical functions of the HP 8901B and the HP 8901A, and should be useful in modifying existing HP 8901A control programs to drive an HP 8901B.

3–8. DATA OUTPUT

Data Output Format

Numeric Data. As shown below, the output data is always in the form of an implicit-point exponential constant. Data is always output in fundamental units (for example, Hz, watts, radians, dB, %, etc.), and the decimal point (not sent) is assumed to be to the right of the tenth digit of the mantissa.

Data values never exceed +9 000 000 000E+01. Output values greater than this are Error Messages.

Output data is displayed using the following format: first the sign, then 10 digits (leading zeros not suppressed) followed by the letter E and a signed two-digit exponent. The last two characters of the string are a carriage return (CR) and a line feed (LF) in string positions 16 and 17. Refer to Table 3–5, “Data Output Examples” for examples.
3-9. HP-IB INFORMATION

HP-IB Capabilities

The interface functions that the HP 8901B implements are defined in Table 3-6, "IEEE Std 488 Interface Function Capabilities". The Modulation Analyzer's HP-IB command capabilities are compatible with the IEEE Standard 488, and the identical ANSI Standard MC1.1.

For more information about the Hewlett-Packard Interface Bus (HP-IB), refer to:
- IEEE Standard 488,
- ANSI Standard MC1.1,
- the Hewlett-Packard Electronic Systems and Instruments catalog,
- the booklets, "Improving Measurements in Engineering and Manufacturing" (HP part number 5952-0058), and "Tutorial Description of HP-IB" (HP part number 5952-0156).

* Instrument also has a Talk Status Only mode
HP-IB Address

**Factory Set Address.** The Modulation Analyzer's HP-IB address is set to decimal 14 at the factory with Talk Only and Listen Only modes disabled. The address can be changed by following the instructions in paragraph 2-3 under “HP-IB Address Selection”.

**Reading the Address.** To display the HP-IB address in decimal on the front panel, select BUS ADRS by pressing the Blue key and then the LOCAL key. The displayed address is in the form:

\[ \text{Addr=NN} \]

Where NN is the two-digit address in decimal. The display will time out after a few seconds.

Refer to “Additional Information”, paragraph 3-11 for more information about HP-IB address.

### 3–10. MODULATION ANALYZER REMOTE CAPABILITIES (IEEE-488)

The capabilities of the HP 8901B in remote operation and their related IEEE Std 488 terms are described in Table 3–7, “Modulation Analyzer Remote Capabilities Table”. The twelve capabilities described there are further described in the paragraphs following the table.

**Table 3–7. Modulation Analyzer Remote Capabilities (1 of 2)**

**Triggering Measurements**

In remote operation, two triggering modes are available: Free-run and Trigger Hold. In Free-run mode, measurements are continually, automatically taken. In Trigger Hold mode, the instrument sets up for the measurement and then waits for a trigger to be received. Valid triggers to use in Trigger Hold are: T2, T3, GET or the CLEAR key.

The instrument goes into Trigger Hold mode after it receives a trigger (except the CLEAR key) even if it was in Free-run before it received the trigger.
TRIGGER MODES (T0 and T1)

**Free Run Mode (T0).** This trigger mode is in effect in local operation, and is also in effect in remote when Trigger Hold mode has not been selected. Measurements are made and measurement data updated as rapidly as settings can be changed without regard for settling of ANY internal or external circuitry or setting changes.

**NOTE**

- *The Modulation Analyzer is always in Free-run trigger mode (T0) after receiving a Device Clear (DCL) message, entering remote from local, or receiving Instrument Preset (IP).*
- *Measurements might NOT be completed if Free-run (T0) is used if there is HP-IB activity between other HP-IB devices (e.g. a controller talking to another instrument) during the measurement. Trigger Immediate (T2) or Trigger with Settling (T3) should be used under these conditions.*

**Trigger Hold Mode (T1).** In Trigger Hold mode, internal settings can be changed by the instrument itself or by the user via the bus; however, the instrument is inhibited from outputting any data to the front-panel key lights and display, or to the HP-IB until it receives a trigger. The following data can be sent before the trigger is received:

- A Service Request message if an enabled LIMIT is reached, or if an HP-IB code error occurs.
- The Status Byte if the instrument is serial polled. (A serial poll, however, will trigger a new measurement, update displays and return the instrument to Trigger Hold.)

Measurement data is replaced with data acquired from subsequent triggered measurement cycles.

**NOTE**

*When a trigger is received, the Modulation Analyzer will not allow its measurement cycle to be interrupted. (Indeed, handshake of bus commands is inhibited until the measurement cycle is complete.)*

**Entering Trigger Hold.** The instrument is placed in this mode after it receives the programming code T1 or after a triggered measurement has been executed. This mode can then be used to set up the instrument for new measurements which are executed by a trigger.

**Triggering Measurements from Trigger Hold.** When a measurement is triggered from Trigger Hold mode, the instrument makes the measurement. The display is updated as the new measurement cycle begins. The Status Byte will be updated (and the Service Request message issued if required) by the events that occur during the new measurement cycle.

Any of the following events will trigger a new measurement cycle when the instrument is in Trigger Hold:

a. instrument receives a trigger,

b. instrument receives its listen address,

c. instrument receives GTL (Go To Local),

After the measurement is made, the instrument waits for the measurement results to be read. While waiting, the instrument can process most bus commands without losing the measurement results. Once the data (measurement results) are read onto the bus, the Modulation Analyzer returns to the Trigger Hold mode.
Leaving Trigger Hold. The instrument leaves Trigger Hold mode when it receives a trigger until the measurement is complete. The Modulation Analyzer also leaves Trigger Hold when it receives:

a. the Free Run code (T0), or
b. when it is returned to local operation,
c. a Device Clear Message (DCL or SDC), or
d. Instrument Preset (IP).

TRIGGERS (T2, T3, GET, and the CLEAR Key)

All triggers are available in both Free Run and Trigger Hold modes, but after a trigger is received (except the CLEAR key), the instrument enters Trigger Hold mode.

Trigger Immediate (T2). When the Modulation Analyzer receives the Trigger Immediate code, it makes one measurement and displays the result without a settling time delay.

Measurement results obtained via Trigger Immediate are normally valid only when the instrument is in a steady, settled state. The first result received from the instrument (using T2) may not be accurate.

Trigger With Settling (T3)

NOTE

- The use of Trigger With Settling does not remove the need to observe the normal warm-up precautions when using either the RF Power, AM, or FM Calibrator. Refer to the procedures “RF Power Calibration”, “AM Calibration”, or “FM Calibration” in the Detailed Operating Instructions.

- If the settling time provided with T3 is not adequate to produce accurate measurements, use T0 (Free-run) and write a sub-program which compares measurement values until they are within a specified tolerance. (Delays, not included in the T3 settling time, in the source and/or the thermocouple in the Power Sensor can prevent accurate measurements.)

Trigger With Settling is identical to Trigger Immediate except the Modulation Analyzer inserts a settling-time delay before taking the requested measurement.

Group Execute Trigger (GET) Message When in remote and addressed to listen, the Modulation Analyzer responds to a Trigger message (GET) by executing a settled-measurement cycle. The Modulation Analyzer responds exactly as if it had received the program code T3 (Trigger With Settling).

Triggering Measurements With the CLEAR Key (CL) When the Modulation Analyzer is in Trigger Hold mode (T1) and not in Local Lockout, the front-panel CLEAR key may be used to issue a Trigger With Settling. Each time the CLEAR key is pressed, the Modulation Analyzer performs a settled-measurement cycle. The CLEAR key will not cause the instrument to enter Trigger Hold mode.

In Free Run mode the CLEAR key will clear the display, but not affect the timing of measurements and will not cause the instrument to enter Trigger Hold.
NOTE

The CLEAR key (CL) does not perform any of the functions of the Clear message (DCL or SDC).

Clear

The Modulation Analyzer responds to the Clear message (DCL and SDC) the same way it responds to Instrument Preset (IP). The Clear message clears any pending Service Request message and clears the SRQ Mask (22.0SP). The settings the instrument will assume after receiving the Clear message are listed below in Table 3–8. Refer to “Instrument Preset” in Detailed Operating Instructions on page 3–209 for more information on the Instrument Preset default conditions.

The Clear message also clears any incomplete message or entries. For example, “M5100” (RF Frequency Measurement, 100, no terminator) would be cleared because no units terminator has been entered.

1 If MHz (code MZ) is selected immediately after the Clear message is received or after power-up, the Modulation Analyzer will tune to 100 MHz.
Remote/Local

Mode Descriptions

Remote Mode. In remote, the Modulation Analyzer’s front-panel controls are disabled except for the LOCAL and CLEAR keys. The LOCAL and CLEAR keys are only disabled by Local Lockout. However, front-panel displays and the output signal at MODULATION OUTPUT/AUDIO INPUT remain active and valid. Two triggering modes are available in remote operation: Free Run and Trigger Hold.

Displays which time out in Local do not time out in Remote. In Remote operation, the CLEAR key will clear the display and works as a trigger when Trigger Hold is used.

Local Mode. In local, the Modulation Analyzer’s front-panel controls are fully operational. When the Modulation Analyzer goes to local operation, the front-panel REMOTE annunciator turns off. However, when the Modulation Analyzer is being addressed (whether in remote or local), its front-panel LISTEN or TALK annunciator lights. Free Run is the only triggering mode available in local operation.

Mode Transitions

Local to Remote Transitions. The Modulation Analyzer switches to remote operation upon receipt of the Remote message. No instrument settings are changed by the transition from local to remote. The Trigger mode will always be Free Run (T0) on entry to remote operation.

Remote to Local Transitions. The Modulation Analyzer always switches to local from remote whenever it receives the Local or the Clear Lockout/Set Local message. No instrument settings are changed by the transition from remote to local, except the Trigger mode will always be reset to Free Run.

If it is not in Local Lockout mode, the Modulation Analyzer switches to local from remote whenever its front-panel LOCAL key is pressed.

NOTE

Remote to Local transitions will not clear a Service Request message.

Local Lockout

Local lockout disables the LOCAL key (and the CLEAR key) and allows return-to-local only under program control.

When a data transmission is interrupted, which can happen if the LOCAL key is pressed, the data being transmitted may be lost. This would leave the Modulation Analyzer in an unknown state. To prevent this, a local lockout is recommended.
Clear Lockout/Set Local

The Modulation Analyzer returns to local operation when it receives the Clear Lockout/Set Local message.

NOTE

Clear Lockout/Set Local can be accomplished by switching the power to STBY and back to ON. Returning to Local operation in this way has the following disadvantages:

- It defeats the purpose of Local Lockout (that is, the system controller will lose control of the Modulation Analyzer).
- Instrument configuration is reset to Power-up conditions listed in the Detailed Operating Instructions under "Instrument Preset" on page 3-209.

Service Request Message (SRQ)

The Service Request Message (SRQ message) is being issued when the SRQ bus line is asserted and the SRQ light on the front panel is lit by the instrument. The Service Request message may be issued under following conditions:

- the instrument requires re-calibration or is uncalibrated,
- there has been a Frequency Offset mode change,
- an enabled limit has been exceeded,
- an instrument error has occurred,
- an HP-IB code error has occurred,
- measurement data is ready to be read.

The Modulation Analyzer uses its Status Byte and the SRQ Mask (Special Function 22) to determine whether or not to issue a SRQ message. Refer to Figure 3-4, “Issuing a Service Request Message” throughout the following discussion of the Service Request Message, SRQ Mask and the Status Byte.

The Service Request Message is asserted when the RQS bit of the Status Byte is set by the instrument. The RQS bit is set automatically when one or more of the other bits in the Status Byte are set. For the bits other than the RQS bit of the Status Byte to be set, those bits must be enabled by the SRQ Mask before the instrument condition which will set them occurs.

The instrument can send the Service Request message in either local or remote operation.

Clearing the Service Request Message. After the Service Request message has been sent, it will be cleared when the Status Byte is cleared which is described below under "Status Byte".
Using the Service Request Message. The Service Request message can be used for detecting instrument conditions and instrument or HP-IB code errors.

The Service Request Message can also be used for signaling measurement data ready. Remote measurements are usually performed simply by triggering measurements, then reading the output data. In certain applications, the controller must control other instruments while the HP 8901B is making a measurement. Using the instrument's ability to issue the Service Request message when data is ready, frees the controller to process other routines until the Modulation Analyzer is ready with data.

See Figure 3-3, "Example Flowchart Using the Service Request Message" for an example of using the SRQ message to signal the controller that the HP 8901B has completed its measurement and the data is ready.
**Definition of the SRQ Mask and Status Byte bits**

User sets to 1 to unmask condition using Special Function 22. HP-IB Code Error bit is permanently unmasked.

1 if condition has occurred and SRQ Mask bit has been set to 1.

1 if one or more other Status Byte bits are 1.

Asserted if RQS bit is 1.

On if SRQ line is asserted and front panel display is updated.

**Figure 3-4. Issuing a Service Request**
SRQ MASK (Special Function 22)

Overview. Special Function 22 is used to set the bits of the SRQ Mask. The set SRQ Mask bits unmask the bits of the Status Byte. At power-up or Instrument Preset, all Status Byte bits are masked except the HP-IB Error Code bit. The appropriate SRQ Mask bits must be set to 1 by the operator to unmask any other Status Byte bit. Refer to Figure 3-4, “Issuing a Service Request” for a graphic example of these relationships.

NOTE

*Bit 1 of the SRQ Mask is permanently set to 1; therefore, an HP-IB code error will ALWAYS generate a Service Request message. This means that the Service Request message CANNOT be disabled.*

Setting the SRQ Mask. Only bits 0, 2, 3, 4 and 5 can be set. Bit 1 (weight=2) is permanently set.

To set the SRQ Mask bits and unmask the Status Byte bits which you want to cause the Service Request Message to be issued:

- Sum the weights of the desired conditions using Table 3-9 below. Use this sum as the suffix of Special Function 22.

NOTE

*S since Bit 1 (HP-IB Code Error) is permanently enabled, if the weight is not summed in, it will be assumed by the instrument, for example 22.0SP is equivalent to 22.2SP.*

- Enter the special function code (and suffix) via the front panel, then select SPCL; or, for remote operation, enter 22.<suffix>SP.

Example. To set the SRQ Mask so that the Modulation Analyzer will issue a Service Request message for all conditions except Data Ready, first compute the Special Function suffix by summing the corresponding weights.

\[ 4 + 8 + 16 + 32 = 60 \]

Key in 22.60SP. (22.62SP would also work because of the permanently set HP-IB Error Code bit.)

</tbody>
</table>

Reading the SRQ Mask. Read the SRQ Mask by entering 22.64SP. This initiates a “measurement” of the mask value which is displayed and available over the bus. This value will be displayed in decimal and can be interpreted using Table 3-9 “SRQ Mask and Status Byte Bit Descriptions”.

Clearing the SRQ Mask. Clear the SRQ Mask by any of the following operations:

- Entering 22.0SP (Remember this will not clear the HP-IB Code Error bit.)
- Sending the Device Clear (DCL) message, sending Instrument Preset (IP) or powering up the instrument.
Status Byte

Overview. The Status Byte bits 0-5 reflect the status of the unmasked Instrument Conditions. Refer to Table 3-9, "SRQ Mask and Status Byte Bit Descriptions" for bit definitions. At power-up and Instrument Preset, the only Status Byte bit which is unmasked is the HP-IB Error Code bit.

The RQS bit (bit 6) is automatically set if any other bit in the Status Byte is set true. When the RQS bit is set, the Service Request message is sent. The front-panel SRQ annunciator turns on at the next front-panel display update. Once any Status Byte bit has been set, it remains set until the Status Byte is read.

If one of these Instrument Conditions occurs, while it is masked by the SRQ Mask, NEITHER the Status Byte bit corresponding to the condition NOR the RQS bit will be set, and the Service Request message will not be sent.

Reading the Status Byte

NOTE

• A Status Byte Bit that is not unmasked by the SRQ Mask will ALWAYS read as a zero when the Status Byte is read. Only an unmasked bit can be read as a one, and then only if its initiating Instrument Condition occurs AFTER it is unmasked.

• Reading the Status Byte is the only accurate way to determine the condition of the SRQ bus line (Service Request message). The SRQ annunciator is only updated as the front panel is updated. It is NOT tied directly to the SRQ bus line.

• The Modulation Analyzer cannot alter the Status Byte while in serial poll mode; therefore, it is not possible to continually poll the Status Byte while waiting for a condition to cause a bit to be set.

• Reading Status of non-existent devices (HP-IB addresses not in use) will hang the HP 8901B HP-IB and requires a Device Clear (DCL) message to clear the bus.

The Status Byte can be read using a serial poll, only if the instrument sends a Service Request Message. Only those bits which are unmasked by the SRQ Mask can be read accurately.

Talk Status Only causes the instrument to only output the Status Byte. Refer to "TALK and LISTEN Status Descriptions" for more information.
Clearing the Status Byte

NOTE

Remote-to-Local transitions will not clear the Status Byte.

Once bits in the Status Byte are set, they can be cleared by the following operations.

- Reading the Status Byte by serial polling AFTER the condition is cleared. If the condition which set the bits persists, those bits and the RQS bit will again be set.
- Sending the Device Clear (DCL) message, presetting or powering up the instrument.
- In Talk Status Only, the Status Byte is cleared each time the one-byte Data message is issued to the bus.
- Sending the Serial Poll Disable (SPD) bus command, or
- Sending the Abort message.

Abort

Abort abruptly terminates all listener/talker activity on the interface bus and prepares all instruments to receive a new command from the controller. Typically this is an initialization command used to place the bus in a known starting condition. The Modulation Analyzer stops listening or talking when it receives the Abort message.

Pass Control/Take Control

The Modulation Analyzer does not respond to the Pass Control/Take Control message because it cannot act as a controller.

Status Bit

The Modulation Analyzer does not implement parallel poll operations and therefore cannot send the Status Bit message. The Status Bit should not be confused with the Status Byte which was discussed previously under "Status Byte".

3-11. ADDITIONAL INFORMATION

Annunciators

REMOTE Light: Lights when the instrument is operating in remote mode. When the Modulation Analyzer goes to local operation, the front-panel REMOTE annunciator turns off.

LISTEN Light: Lights when the instrument is addressed to Listen.

TALK Light: Lights when the instrument is addressed to Talk.
**SRQ Light:** Lights when the Service Request message has been sent (SRQ line true), and the front panel has been updated.

**Reading the HP-IB Address Switch and SRQ Status**

The HP-IB switch sets the instrument address and the Talk and Listen modes of the instrument. To display the state of the HP-IB address switch and the SRQ Line in binary, enter 21.0SP.

This display does not time out. To clear the instrument display, press the CLEAR key.

The format of the display is as follows:

```
AAAAA.TLS
```

where AAAAA is a five-bit binary address with leading zeros blanked and TLS represent the status of the TON switch, LON switch and SRQ bus line respectively.

**NOTE**

- If T and L are both 1, the instrument is set to Talk Only (Talk Only overrides Listen Only).
- If all A bits are 1 and T is 1, the instrument will Talk Status Only (that is, output the status byte only).

A list of possible conditions of the TLS digits of the display is provided in the following table:

**Table 3-10. TLS Table**

<table>
<thead>
<tr>
<th>Operating Mode</th>
<th>T Digit</th>
<th>L Digit</th>
<th>S Digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Talk and Listen</td>
<td>0</td>
<td>0</td>
<td>1 or 0</td>
</tr>
<tr>
<td>Talk Only</td>
<td>1</td>
<td>1 or 0</td>
<td>1 or 0</td>
</tr>
<tr>
<td>Talk Status Only</td>
<td>1*</td>
<td>1 or 0</td>
<td>1 or 0</td>
</tr>
<tr>
<td>Listen Only</td>
<td>0</td>
<td>1</td>
<td>1 or 0</td>
</tr>
</tbody>
</table>

*Instrument address must be 11111 in binary. (31 in Decimal.)*

**Example.** If 1110.001 is the address displayed, then the HP-IB address is 1110 in binary (that is, 14 in decimal). The T digit is “0”, and the L digit is “0” indicating that the instrument is set to be able to Talk and Listen. The S digit is 1 indicating that the instrument is issuing a Service Request Message.

For the same example, if the BUS ADRS key is used, Addr = 14 will be displayed. (No information about Talk Only, Listen Only, or SRQ is displayed.)

**Setting the HP-IB Address.** The Modulation Analyzer’s talk and listen addresses are switch selectable as described in paragraph 2-7. Refer to Table 2-2 for a comprehensive listing of all valid HP-IB address codes.

**Updating the HP-IB Address Display.** The HP-IB address display is continuously updated. When the switch setting is changed, the result is immediately visible on the display.
TALK and LISTEN Status Descriptions

Talk Only Mode. If the internal address switches are set to a valid address and the TON (Talk Only) switch is set to "1", the Modulation Analyzer is placed in the Talk Only mode. This mode causes the instrument to output data each time a measurement is made. Each time the measurement is completed, data will be output to the bus unless the listening device is not ready for data. If the listener is not ready, and the Modulation Analyzer is in Free Run mode (T0), another measurement cycle is executed.

Talk Status Only Mode. If the five internal address switches and the TON (Talk Only) switch are set to "1", the Modulation Analyzer is placed in the Talk Status Only mode. In this mode the instrument is configured to send a one-byte data message whenever the bus is in the data mode. The byte sent is an exact copy of the Status Byte. Each time this byte is successfully sent on the bus, the internal Status Byte is cleared. The Data Valid (DAV) handshake line is pulsed each time the one-byte Data message is sent.

Listen Only Mode. Listen Only mode is provided to allow the Modulation Analyzer to accept programming from devices other than controllers (for example, card readers).

If the internal LON (Listen Only) switch is set to "1" and the TON (Talk Only) switch is set to "0", the Modulation Analyzer is placed in the Listen Only mode when the remote enable bus control line (REN) is set true. The instrument then responds to all Data messages, and the Trigger, Clear, and Local Lockout messages. However, it is inhibited from responding to the Local or Abort messages and from responding to a serial poll with the Status Byte message.

Code Execution in the Modulation Analyzer

Some things to consider when programming the HP 8901B are listed below. The following discussion of the Software Supervisor is included to elaborate on these considerations.

- Every two-letter command is acted upon, in order, in software state.
- Hardware State equals the Software State only after the end of the HP-IB code string AND a pause occurs allowing the instrument to implement the commands it has received (e.g., time delay between code strings when data is read from the instrument).
- Only one measurement mode may be loaded from Software state to Hardware state at a time; e.g., M2 D2 P1 H1 L2. For fail-safe operation, only use one measurement code per code string before reading a measurement back from the instrument. Refer to Table 3-13, "Measurement Modes and Codes" for a complete list of all the functions defined as Measurement Modes.
- Keyboard or HP-IB commands may not be implemented in hardware state during a measurement if the instrument decides the command is not significant to a particular measurement. Refer to Table 3-13, "Measurement Modes and Codes" and Table 3-14, "Measurement Modifiers" for more information.

The Software Supervisor is the program that controls overall instrument operation and controls the implementation of commands received from the external controller. (See Figure 3-5, "Software Supervisor Flowchart"). It is a loop that is continuously executed, with measurements made near the end after checks for proper frequency tuning, proper RF and IF level, and correct audio range. After arithmetic manipulation (e.g., for the RATIO function), the program loops back up to display the measurement.

The Software Supervisor controls the setup of the instrument for a measurement by making use of two concepts called Software State and Hardware State. Each of these is updated independently. The Software State is located in RAM and contains a software image of the state of the instrument. On power-up, the initialization procedure loads the initial Software State from ROM. (Refer to "Instrument Preset" in the Detailed Operating Instructions on page 3-200 for a description of the initial instrument setup.)
conditions.) The [Set Up Hardware] block in the supervisor is where the hardware state is made to conform with the software state.

The hardware state is the actual, current state of the internal settings of the instrument and is only updated when enough time is allowed between commands for the Software Supervisor measurement loop to be completed successfully without interruption; e.g., when a trigger is received.

The [Frequency Tuning], [Signal Leveling], and [Audio Ranging] blocks manipulate hardware as well and also verify that the instrument is adjusted to make an accurate measurement. A measurement is not made until all blocks are successfully completed in succession. If a block is not completed, a negative [Continue?] decision after that block then forces the program back to the top of the supervisor, bypassing the measurement for that loop.

In a normal, stable measurement cycle, the program takes the [Measurement Display] branch at the top of the supervisor and so avoids the extra time associated with the [Set Up Hardware] block. However, if the program loops back before taking a measurement, or if an error condition exists, the [Non-Measurement Display] branch will be traversed. This will light an appropriate display, which is usually "- - - ", and send the program back through the [Set Up Hardware] block.

After power-up, the external system controller can be thought of as a medium through which the user requests a certain instrument setup which is first implemented in software state and then in hardware state. Controller commands ( [Keyboard or HP-IB interrupts] ) are treated as non-returnable interrupts and break the flow around the Software Supervisor loop, forcing the internal microprocessor to execute a short program to change the software state and then return to the loop as shown in the diagram. The commands applicable to the measurement mode are implemented in software state and then in hardware state at the next [Set Up Hardware].

**NOTE**

Controller routines modify only the software state and do not affect the hardware immediately.

Since a [Keyboard or HP-IB interrupt] can interrupt the Supervisor at any point and return it to the point in the loop before [Set Up Hardware], these interrupts abort the current measurement and start a new measurement cycle.

The actual instrument setup is guaranteed to conform to the Keyboard request only at the moment a measurement is taken ( [Measure] ).

3-12. BASIC FUNCTIONAL CHECKS OF THE MODULATION ANALYZER

Description
Using a signal generator, an oscilloscope, and a sensor module, the overall operation of the Modulation Analyzer is verified.

Equipment

Oscilloscope ................................................................. HP 1740A
Sensor Module .............................................................. HP 11722A
Signal Generator ......................................................... HP 8640B Option 001 and 002

The HP 8656B, HP 8662A, HP 8663A, HP 8654A or HP 8654B can also be used if an HP 8640B Option 001 and 002 is not available. However, with these other signal generators you will need to modify some tests.

Procedure

Preliminary Check
1. Connect the multi-conductor cable of the sensor module to the SENSOR input connector. Connect the RF coaxial cable of the sensor module to the INPUT 50Ω connector (see Figure 3-6). Select INSTR PRESET (Blue Key, AUTOMATIC OPERATION). Observe the front-panel LED annunciators, display segments and decimal points, and key lights. All LEDs should light for approximately 10 seconds at turn on and then all should momentarily turn off.

2. After the turn-on sequence, the instrument should display “—”. The MHz annunciator, the FM annunciator under MODULATION OUTPUT, the AUTO TUNING annunciator (under the TRACK MODE key), and the FREQ key should be lighted.

RF Power Calibration Check
3. Connect the sensor module input to the RF POWER CALIBRATION OUTPUT connector. (See Figure 3-6.)

4. Press the RF POWER key. If the instrument does not display Error 15, proceed with step 6. If the instrument displays Error 15 (indicating the RF power calibration factors have not been entered), proceed with step 5.

5. If the instrument displays Error 15, enter the RF power calibration factors that are given on the cover of the sensor module. (Note that a software driven alternative is available. See RF Power for a program list in BASIC for the HP Series 200 computers.):
   a. Enter the reference calibration factor by keying in 37.3 and pressing the SPCL key. Then, key in the value of the reference calibration factor and press the Blue key then the % CAL FACTOR key (the MHz key).
   b. Enter each frequency/calibration factor pair by first keying in 37.3 and pressing the SPCL key. Next, key in the frequency (in MHz) and press the MHz key. Then, key in the value of the calibration factor and press the Blue key then the % CAL FACTOR key.

NOTE
Error 15 will continue to be displayed until the Modulation Analyzer is able to interpolate between a frequency/calibration factor pair from those pairs entered. (For more information, refer to RF Power Calibration and RF Power Calibration Factors in the Detailed Operating Instructions in this section.)
6. Press the ZERO key. "--- --- ---" should be displayed for approximately 15 seconds, 0.00 00 W should then be displayed briefly, and then a value less than 3.0 -06 W (that is, 3.0 µW) should be displayed. (Ignore the RECAL and UNCAL annunciators if they are displayed.)

7. Press the CALIBRATE key. When a value appears in the display, press the Blue key and SAVE CAL key (the CALIBRATE key). The display should show between 0.999 -03 and 1.000 -03 W (that is, 0.999 and 1.000 mW) or between 999 -06 and 1000 -06 W (that is, 999 and 1000 µW). The RECAL and UNCAL annunciators should be off. Turn off the calibrator by pressing the CALIBRATE key again.

**RF Power Check**

8. Set the signal generator to 100 MHz CW at -10 dBm (as measured on its level meter).

9. Connect the input of the sensor module to the RF output of the signal generator. Connect the MODULATION OUTPUT/AUDIO INPUT to the vertical input of the oscilloscope. (See Figure 3-7.)

10. Press the LOG/LIN key to display power in dBm. The Modulation Analyzer should display between -11.00 and -9.00 dBm.

**RF Peak Level Check**

11. Key in 35.0 and press the SPCL key (uses a peak detector to measure power). The Modulation Analyzer should display between -16.00 and -6.00 dBm.

**Frequency Check**

12. Press the FREQ key. Key in 7.1 and press the SPCL key to set the RF frequency resolution to 10 Hz. Set the signal generator’s frequency as shown in the following table. For each frequency, allow the Modulation Analyzer to tune to the signal then compare the signal generator's frequency display with the Modulation Analyzer's display. The two displays should agree within the limits indicated.

<table>
<thead>
<tr>
<th>Signal Generator Frequency (MHz)</th>
<th>Frequency Difference Limits (±Hz)</th>

</tr>
<tr>
<td>800</td>
<td>3200</td>
</tr>
</tbody>
</table>

13. Set the signal generator frequency to 50 MHz. When the Modulation Analyzer has tuned to the signal, press the MHz key to disable the automatic tuning and enable manual tuning. Press the S (Shift) key and the FREQ ERROR key (the FREQ key). The Modulation Analyzer should display between -1 and 1 kHz.

14. Key in 100 and press the † kHz key. The Modulation Analyzer should display between -101 and -99 kHz. Key in 7.0 and press the SPCL key to return the RF frequency resolution to automatic selection.
**Figure 3-6. RF Power Calibration Setup**

**Figure 3-7. RF Power Check Setup**
Track Mode Tuning Check

15. Press the AUTOMATIC OPERATION key then the FREQ key. Press the TRACK MODE key. Manually sweep the signal generator's frequency to 64 MHz. The Modulation Analyzer's frequency display should track the frequency as it changes. Press the TRACK MODE key again to turn off the function.

AM and FM Calibration Check

16. Connect the input of the sensor module to the AM/FM CALIBRATION OUTPUT connector. (See Figure 3–8.)

![Diagram of HP 8901B Modulation Analyzer with sensor module connected](image)

**Figure 3–8. AM and FM Calibration Check Setup**

17. Press the AM key then the CALIBRATE key. After approximately 20 seconds, the AM calibration factor should be displayed. The displayed value should be between 99.00 and 101.00%.

18. Press the FM key then CALIBRATE key. After approximately 20 seconds, the FM calibration factor should be displayed. The displayed value should be between 99.00 and 101.00%. Press the CALIBRATE key again to turn off FM calibration. (If you remove the sensor with the calibrator still on it might return Error 08.)

AM Check

19. Reconnect the sensor module input to the signal generator's output. (See Figure 3–9.)

20. Press the Modulation Analyzer's MHz key. Set the signal generator for 50% AM (as measured on its AM meter) at a 1 kHz rate.

21. Press the AM key. The Modulation Analyzer should display between 46.0 and 54.0%.

22. Set the signal generator's AM to 25% (as measured on its AM meter). The Modulation Analyzer should display between 22.00 and 28.00%
FM and Phase Modulation (ΦM) Checks

23. Set the signal generator's AM off and set FM to 50 kHz peak deviation (as measured on its FM meter) at a 1 kHz rate. Press the FM key. The Modulation Analyzer should display between 45.0 and 55.0 kHz.

24. Adjust the signal generator's FM peak deviation for 50 kHz as displayed by the Modulation Analyzer.

25. Press the ΦM key. The instrument should display between 45.0 and 55.0 rad.

FM De-emphasis Check

26. Press the FM key. Press the RATIO key. If the display is in dB, press the LOG/LIN key to display %. The instrument should display between 99.8 and 100.2% REL. The oscilloscope should show a sinusoidal waveform with a peak-to-peak amplitude between 0.9 and 1.1V and a period of 1 ms.

27. Press the LOG/LIN key. Press the RATIO key. Press the PRE-DISPLAY key. Set the FM rate as listed in the following table. For each setting, perform the following steps:

   a. Set the FM DE-EMPHASIS off if it is on. (Leave PRE-DISPLAY on.)
   b. Set the signal generator's FM modulation rate to a value approximate to that listed in the table.
   c. Press the RATIO key to establish a reference of 0 dB.
   d. Press the FM DE-EMPHASIS time constant key listed in the table.
   e. Adjust the modulation rate (but not the level) until the displayed modulation is -3.0 dB.
   f. Press the S (Shift) key then press the AUDIO FREQ key (the AM key). The Modulation Analyzer should display a rate within the limits listed. Also, the oscilloscope waveform should change proportionately with the display. (Allow for a times 10 amplitude at the output of MODULATION OUTPUT/AUDIO INPUT when FM DE-EMPHASIS is set to 750 μs.)
Audio Frequency and Audio Filters Check

28. Set FM DE-EMPHASIS and PRE-DISPLAY off. Set the FM rate as listed in the following table. For each setting, perform the following steps:

   a. Set the HP FILTER and LP FILTER to ALL OFF.
   b. Set the signal generator’s FM rate as listed in the table.
   c. Press the FM key then press the RATIO key to establish a reference of 0 dB.
   d. Set the HP or LP FILTER as listed in the table, and fine adjust the FM rate for a reading of -3.0 dB REL.
   e. Press the S (Shift) key then the AUDIO FREQ key and note the FM rate. The Modulation Analyzer should display a rate within the limits listed.

Audio Distortion and SINAD Check

29. Press the AM key and set the LP FILTER to ALL OFF. Set the signal generator’s FM off, and set the AM depth to 50% (as measured on the Modulation Analyzer’s display) at a 1 kHz rate. Press the S (Shift) key then the AUDIO DISTN key (the FM key). The displayed distortion should be less than 3%. (The display should also indicate 1 kHz. If 400 Hz is displayed, press the Blue key then the 400 Hz DISTN key (the PEAK key)).

30. Set the signal generator’s AM for a 400 Hz rate. Press the Blue key then the 400 Hz DISTN key (the PEAK key). The displayed distortion should be less than 3%.

31. Press the LOG/LIN key to display the distortion in dB. Key in 29.0 and press the SPCL key. The displayed SINAD should be greater than 30 dB.

External Audio RMS Level Check

32. Connect the audio (AM or trigger) output of the signal generator to the input of the oscilloscope. (See Figure 3-10.) Set the signal generator’s audio output level for 3 Vpp as read on the oscilloscope.

33. Connect the audio output of the signal generator to the MODULATION OUTPUT/AUDIO INPUT of the Modulation Analyzer. (See step 33 of Figure 3-10.) Key in 30.0 and press the SPCL key. If the display is in dB V, press the LOG/LIN key to display V. The Modulation Analyzer’s displayed level should be between 0.95 and 1.17V.
Audio Detector Check

34. Disconnect the signal generator's audio output. Press the FM key. Set the signal generator's AM off and set the FM on with a peak deviation of 50 kHz and a rate of 1 kHz. Press the RATIO key then the LOG/LIN key to % to establish a reference of 100%. Set DETECTOR to PEAK-. The Modulation Analyzer should display between 95 and 105% REL depending upon the signal generator's FM distortion.

35. Set DETECTOR to PEAK±/2 by pressing both the PEAK+ and PEAK− keys simultaneously. The Modulation Analyzer should display a value between 100% and the value read in step 34.

36. Press the AVG key. The instrument should display between 69.3 and 72.1% REL. Turn the ratio function off by pressing the RATIO key again.

37. Press the PEAK+ key then press the PEAK HOLD key. Switch the signal generator's FM off. The Modulation Analyzer's display should retain the largest value obtained after pressing PEAK HOLD. Turn off the peak hold function by pressing the PEAK+ key.

IF Level Check

38. Press the S (Shift) key then the IF LEVEL key (the ΦM key). The Modulation Analyzer should display between 99.9 and 100.1%.

IF Frequency and LO Frequency

39. Set the signal generator to 100.000 MHz CW at 0 dBm. (Accurately set its frequency.) Press the AUTOMATIC OPERATION key then key in 34.0 and press the SPCL key to display the IF frequency. The frequency displayed should be between 1.45 and 1.55 MHz.

40. Key in 33.0 and press the SPCL key to display the LO frequency. The frequency displayed should be between 101.45 and 101.55 MHz.

41. Key in 3.1 and press the SPCL key. (Special Function 3.1 switches the IF bandwidth back to 455 kHz.) The frequency displayed should be between 100.44 and 100.46 MHz.
Tuned RF Level and RF High-Pass Filter Check

42. Set the signal generator to 5.25 MHz CW at 0 dBm. Press the TUNED RF LEVEL key (SHIFT, RF LEVEL). The display should read between 0.500 and 2.000 – 03 W (that is, between 0.5 and 2 mW).

43. Press the RATIO key. If the display is in % REL, press the LOG/LIN key to display dB REL. Key in 3.3 and press the SPCL key (to insert the RF high-pass filter). The Modulation Analyzer should display between –2 and –8 dB REL. Turn off the ratio function by pressing the RATIO key again. Key in 3.0 and press the SPCL key to return the RF high-pass and IF filter selection to automatic.

Error Check

44. Set the signal generator to 200 MHz CW at 0.0 dBm. On the Modulation Analyzer, press the AUTOMATIC OPERATION key then press the FM key. Press the PEAK+ key. After the Modulation Analyzer is tuned, press the RANGE HOLD key. Key in 100 then press the ↑ kHz key. The Modulation Analyzer should display Error 01. Press the RANGE HOLD key again to turn off the function.

45. Press the ↓ kHz key. Key in 2.1 and press the SPCL key. Set the signal generator's FM on and adjust the peak deviation for 5 kHz (as read on its FM meter). The Modulation Analyzer should display Error 04.

46. Key in 8.4 and press the SPCL key. The instrument should display Error 07.

High-Selectivity Level Check (Option Series 030)

47. Set the signal generator to 10 MHz CW at 0.0 dBm. On the Modulation Analyzer, press the Blue key then press the INSTR PRESET key (the AUTOMATIC OPERATION key) to preset the instrument. Key in 24.0 then press the SPCL key to initialize the high-selectivity level measurement.

48. Key in 24.1 then press the SPCL key. Slowly fine tune the signal generator up and down until a maximum level is found. At that frequency key in 24.2 then press the SPCL key. (This establishes an IF level reference.)

49. Slowly fine tune the signal generator down until the Modulation Analyzer displays –6.0 dB. Note the signal generator's frequency.

50. Slowly fine tune the signal generator up until the Modulation Analyzer again displays –6.0 dB. Subtract the displayed frequency from the frequency of step 49. The difference should be between the limits shown in the following table for the option combination given.

<table>
<thead>
<tr>
<th>Option Combination</th>

</tbody>
</table>

51. On the Modulation Analyzer, press the Blue key then press the INSTR PRESET key. Key in 24.0 then press the SPCL key.
52. Key in 24.3 then press the SPCL key. Slowly fine tune the signal generator up and down until a maximum level is found. At that frequency key in 24.4 then press the SPCL key. (This establishes an IF level reference.)

53. Slowly fine tune the signal generator down until the Modulation Analyzer displays −6.0 dB. Note the signal generator's frequency.

54. Slowly fine tune the signal generator up until the Modulation Analyzer again displays −6.0 dB. Note the signal generator's frequency. Subtract the displayed frequency from the frequency of step 53. The difference should be between the limits shown in the following table for the option combination given.

<table>
<thead>
<tr>
<th>Option Combination</th>
<th>Frequency Difference Limits (kHz)</th>

External LO Check (Option Series 030)

56. Set the signal generator to 51.50 MHz CW at 0 dBm. Connect the signal generator's output to the rear-panel LO INPUT connector. Connect the sensor module’s input to CALIBRATION RF POWER OUTPUT connector. (See Figure 3–11.)

57. On the Modulation Analyzer, key in 45.16 and press the SPCL key then key in 23.1 SPCL and press the SPCL key. (This turns on the RF power calibrator and switches the LO to external.) Key in 50 then press the MHz key. The display should read between 48 and 52 MHz.
3–13. BASIC FUNCTIONAL CHECKS OF THE HEWLETT-PACKARD INTERFACE BUS (HP-IB)

Description

The following ten procedures check the Modulation Analyzer’s ability to process or send all of the applicable HP-IB messages described in paragraphs 3–12 through 3–31. In addition, the Modulation Analyzer’s ability to recognize its HP-IB address is checked and all of the bus data, handshake and control lines except DIO8 (the most significant data line which is not used by the Modulation Analyzer) are set to both their true and false states. These procedures do not check whether or not all Modulation Analyzer program codes are being properly interpreted and executed by the instrument; however, if the front panel operates as expected, the program codes, in all likelihood, will be correctly implemented.

The validity of these checks is based on the following assumptions:

- The Modulation Analyzer performs properly when operated via the front-panel keys (that is, in local mode). This can be verified with the preceding Basic Functional Checks of the Modulation Analyzer in paragraph 3–11.

- The bus controller properly executes HP-IB operations.

- The bus controller’s HP-IB interface properly executes the HP-IB operations.

If the Modulation Analyzer appears to fail any of these HP-IB checks, the validity of the above assumptions should be confirmed before attempting to service the instrument.

The select code of the controller’s HP-IB interface is assumed to be 7. The address of the Modulation Analyzer is assumed to be 14 (its address as set at the factory). This select code-address combination (that is, 714) is not necessary for these checks to be valid. However, the program lines presented here would have to be modified for any other combination.

These checks are intended to be as independent of each other as possible. Nevertheless, the first four checks should be performed in order before other checks are selected. Any special initialization or requirements for a check are described at its beginning.
Initial Setup

The test setup is the same for all of the checks. Connect the Modulation Analyzer to the bus controller via the HP-IB interface. Do not connect any equipment to any of the Modulation Analyzer’s input connectors.

Equipment

HP-IB Controller .................. HP 9825A/98213A (General and Extended I/O ROM)
or ........................................ HP 9835A/9832A (I/O ROM)
or ........................................ HP 9845A (with HP-IB capability)
HP-IB Interface ...................... HP 98034A (use “revised” version with 9835A and 9845A)

The HP 9825A uses HPL. The HP 9835A and HP 9845A use BASIC. You can also use HP Series 200 Controllers which use BASIC. (Code differences exist between the BASIC used by the HP 9835A and HP 9845A and the BASIC used by the HP Series 200 Controllers. These code differences are specified in the procedure.)

Procedures

Using the table of instructions under each function, read the description of the purpose of the commands and then enter the commands appropriate to your controller exactly as described. Check that the instrument responds correctly.

Address Recognition Check. This check determines whether or not the Modulation Analyzer recognizes when it is being addressed and when it is not. This check assumes only that the Modulation Analyzer can properly handshake on the bus. Before beginning this check, set the Modulation Analyzer’s POWER switch to STBY, then to ON.

Remote/Local Messages and the [LOCAL] Key Check. This check determines whether the Modulation Analyzer properly switches from local to remote control, from remote to local control, and whether the [LOCAL] key returns the instrument to local control. This check assumes that the Modulation Analyzer is able to both handshake and recognize its own address. Before beginning this check, select 40.0 SPCL.
### Sending the Data Message Check (Data Output)
This check determines whether or not the Modulation Analyzer properly issues Data messages when addressed to talk. This check assumes that the Modulation Analyzer is able to handshake and recognize its own address. Before beginning this check, select 40.0 SPCL.

<table>

Local Lockout and Clear Lockout/Set Local Messages Check. This check determines whether or not the Modulation Analyzer properly receives the Local Lockout message, disabling all front-panel keys. The check also determines whether or not the Clear Lockout/Set Local message is properly received and executed by the Modulation Analyzer. This check assumes that the Modulation Analyzer is able to handshake, recognize its own address, and properly make the remote/local transitions. Before beginning this check, select 40.0 SPCL.

3-14. DETAILED OPERATING INSTRUCTIONS

Introduction to the Section

These Detailed Operating Instructions provide a complete operating reference for the Modulation Analyzer user. As an operating reference, this section contains all relevant information regarding operating the Modulation Analyzer. (If you intend to operate the Modulation Analyzer remotely, the Remote section contains information about how the Modulation Analyzer interacts with a controller.)

This section is intended to be a reference document for users who have already learned how to make basic measurements using the HP 8901B Basic Operation and Application Guide (included in this section; part number 08901-90117). For your application, the HP 8901B Basic Operation and Application Guide may be all you need to make measurements. However, the Detailed Operating Instructions will enable you to use the full capabilities of the Modulation Analyzer.

Section Organization

The section is organized into tabbed sections oriented toward specific measurement types. Each tabbed section contains all measurement capabilities and support functions involved in making that measurement type.

For example, the tabbed section, Modulation, contains all information about specific AM, FM, and FM measurements as well as:

- selecting an audio detector,
- selecting an audio filter,
- selecting an audio range,
- using the Modulation Output, and
- accounting for residual noise effects.

How To Find Information About a Specific Measurement

Behind most tabs is a table of contents for that tabbed section. Use this table of contents to find the Detailed Operating Instruction relevant to the measurement you are trying to make.

For example, if looking for information about making an FM measurement, find the tab “Modulation”. Find the table of contents behind that tab. Then look up the Detailed Operating Instruction, FM. Turn to the page listed for that instruction. Within that Detailed Operating Instruction, you will find the following categories of information:

Functions   lists all the Modulation Analyzer functions to be discussed that pertain to FM.

Description introduces the FM measurement and any of the listed Functions.

Procedure provides specific instructions about making the FM measurement.

HP-IB lists all the Hewlett-Packard Interface Bus (HP-IB) codes relevant to making the FM measurement in remote operation.

Measurement Technique describes the basic circuitry used to make the measurement. Sometimes, this information can provide an experienced user with a basis for adapting the Modulation Analyzer to varied measurement situations.

Comments provide miscellaneous information that is not essential to the basic measurement but could be valuable to an experienced user attempting to use the Modulation Analyzer in measurement situations not explicitly described in the “Procedure”.

RF Power

FUNCTIONS

RF POWER, % CAL FACTOR, ZERO, CALIBRATE, SAVE CAL, DISPLAY FREQ, Special Function 37 (Calibration Factors: RF Power)

DESCRIPTION

The Modulation Analyzer can make calibrated measurements of RF and microwave power levels when used with a power sensor or sensor module.1 (Refer to Table 1–1, Specifications for a list of compatible power sensors. Note that the Modulation Analyzer automatically determines the type and sensitivity of the sensor.) Absolute level accuracy and sensitivity are determined by the particular power sensor selected and the SWR of the signal source.

Calibration

Specified measurement accuracy is ensured if calibration is performed with each power sensor. Calibration consists of four steps:

1. Entering the 1 mW, 50 MHz reference calibration factor and the frequency-dependent calibration factors from the power sensor’s calibration label.

   Calibration factors (cal factors) are used to compensate the external power sensor’s frequency response relative to a 1 mW reference calibration made at 50 MHz using the Power Reference Oscillator. The cal factors, including a reference cal factor, are usually printed on the power sensor or sensor module.

   Cal factors can be entered and stored in an internal table (Automatic Cal Factors) in the instrument’s non-volatile memory. The table is automatically accessed during RF power measurements (after the Modulation Analyzer has tuned to the frequency) to correct for the non-linear frequency response of the power sensor. If no entry in the table directly corresponds to the frequency being measured, the Modulation Analyzer derives a cal factor through linear interpolation using the nearest calibration points in the table (on either side of the frequency being measured). Up to sixteen frequency/calibration-factor pairs can be entered (plus the reference cal factor).

   You can enter, review, and manually alter cal factors. Also, you can manually override the selection of automatic cal factors without altering the table.

2. Zeroing the power sensor.

   The zeroing process cancels any inherent dc offset that may be present within the power sensor under zero power condition.

3. Configuring the Modulation Analyzer to measure the power from the 1 mW RF power reference (the 1 mW Power Reference Oscillator).

   The internal 1 mW Power Reference Oscillator, used in RF power calibration is an extremely amplitude-stable RF power source that has been set to 1 mW (0 dBm) into 50Ω, traceable to the National Bureau of Standards (NBS). This power reference enables the Modulation Analyzer to precisely determine the sensitivity of the external power sensor at 50 MHz (voltage out vs. power in).

4. Scaling subsequent power measurements to the 1 mW calibration.

   In scaling, the Modulation Analyzer equates the output from the power meter to 1 mW.

---

1 A sensor module contains a power sensor path and a through path for RF measurements as well as an RF switch to switch between the two paths. The Modulation Analyzer controls the switching of the input signal depending on the measurement selected.
PROCEDURE

Determine Cal Factor Status

Determine the status of the calibration factors and enter new calibration factors if necessary. Connect the power sensor or sensor module to the Modulation Analyzer’s SENSOR input. (The power sensor cable need not be connected to the source at this time.)

1. Select RF POWER. If Error 15 is displayed, no calibration factors have been entered. Enter calibration factors as described in steps a and b below. If Error 15 is not displayed, proceed to step 4.

2. Enter the reference cal factor (the reference cal factor is the cal factor for 50 MHz; all other cal factors are relative to it):
   37.3 SPCL, reference cal factor value (printed on a label on the power sensor),
   % CAL FACTOR (Blue Key, MHz).

   Example: Enter a reference cal factor of 98.5% into the Automatic Cal Factor table.

   37.3 SP 98.5 CF

   Code Function Code

3. Enter each frequency/cal-factor pair:
   37.3 SPCL, frequency value (in MHz), cal-factor value, %CAL FACTOR (Blue Key, MHz).
   Repeat this step until all frequency/cal-factor pairs have been entered.

   • Disregard Error 15 if it is displayed during cal factor entry.

   • If an error is made during entry of any value, select CLEAR and immediately re-enter the correct value.

   Example: Enter a cal factor of 99.0% at a frequency of 1 MHz.

   Code Function Data Function

3-72 RF Power
4. Verify that the Automatic Cal-Factor table was entered correctly.

Recall the reference cal factor and compare the value to that on the label on the power sensor:
37.5 SPCL, % CAL FACTOR (Blue Key, MHz)

5. Recall each frequency/cal-factor pair and compare each value to its counterpart on the power sensor:
37.6 SPCL;
DISPLAY FREQ (Blue Key, ‰) to display the frequency value,
% CAL FACTOR (Blue Key, MHz) to display the cal factor value.
Repeat this step until all frequency/cal-factor pairs have been verified.

- Attempting to read beyond the end of the table results in Error 26.

- To replace an existing cal-factor entry, enter the new cal factor at the frequency previously used in the entry (refer to step 1).

- To remove an existing cal factor from the table in memory, enter 0% as the cal factor at the frequency previously used in the entry (refer to step 1).

6. To re-enter the Automatic Cal Factor mode, select AUTOMATIC OPERATION, then reselect RF POWER.

**Zero the Sensor**

If the instrument has just been turned on, allow at least a half-hour continuous operation. Connect the sensor between the Modulation Analyzer's SENSOR input and CALIBRATION RF POWER OUTPUT.

7. Select ZERO. If a power sensor is being used (rather than a sensor module) the CALIBRATE key light must be off for proper zeroing. (A sensor module has an internal switch that will automatically switch out any input signal.) After a few seconds, 0.0 00 W is displayed, then a measurement result of near zero power is displayed.

**Configure the 1 mW RF Power Reference**

8. Select CALIBRATE. The instrument displays the power from the RF power reference using the last calibration scaling.

**Enable Calibration Scaling**

9. Select SAVE CAL (Blue Key, CALIBRATE). Read 1.000 mW. The calibration scaling stays in effect until another SAVE CAL operation is done. Select CALIBRATE again to turn off the calibrator (CALIBRATE key light off). (If the calibrator is not turned off, the RF power measurements will not range properly.)

(Note that when calibrating the Modulation Analyzer over HP-IB, use T3 settling time code between the CALIBRATE (C1) and SAVE CAL (SC) codes. For example: C1T3SC.)

THE MODULATION ANALYZER IS NOW CALIBRATED.
Measure power levels by selecting RF POWER.
### Summary of Special Function 37

<table>
<thead>
<tr>
<th>SPCL</th>
<th>Special Function Description</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 37.0 | Selects the Automatic Cal Factor mode. This enables the Modulation Analyzer to automatically select cal factors based on those entered using Special Function 37.3. | • This mode is selected upon instrument power-up and with Automatic Operation.  
• Can be keyed from any Measurement mode. |
| 37.1 | Selects the Manual Cal Factor Mode. This enables the user to override the automatic selection of cal factors.  
Procedure: To enter a manual cal factor, select: 37.1 SPCL, cal factor value, % CAL FACTOR (Blue Key, MHz) | • If no cal factor is entered, the Modulation Analyzer uses the cal factor recalled last from the table as the manual entry.  
• The manual cal factor remains in effect when the Modulation Analyzer is retuned.  
• The automatic cal factor table is not affected by any manual cal factor entries.  
• Can be keyed only after selecting RF POWER. |
| 37.2 | Displays the status of the cal factor mode (0=A=Automatic, 1=Manual). | • Can be keyed from any Measurement mode. |
| 37.3 | Prepares to enter a reference cal factor or a frequency/cal-factor pair into the appropriate table in memory.  
Procedures: To enter the reference cal factor, select: 37.3 SPCL, cal factor value, % CAL FACTOR (Blue Key, MHz).  
To enter each frequency/cal-factor pair, select: 37.3 SPCL, frequency value (in MHz), MHz cal factor value, % CAL FACTOR (Blue Key, MHz). (It’s unnecessary to wait until the values are displayed before continuing with subsequent entries.) (See examples in this section.) | • If an error is made during entry of any value, select CLEAR and immediately re-enter the correct value.  
• To replace an existing cal factor entry, enter the new cal factor at the frequency previously used in the entry. The Modulation Analyzer will automatically save the entry in the correct order in the table.  
• To remove an existing cal factor from the table in memory, enter 0% as the cal factor at the frequency previously used in the entry.  
• Can be keyed from any Measurement mode. |
| 37.4 | Displays the number of entries in the table. | • The number of table entries displayed also includes the reference calibration factor.  
• Can be keyed from any Measurement mode. |
| 37.5 | Prepares to recall the reference cal factor from the table.  
Procedure: To display the reference cal factor, select: 37.5 SPCL, % CAL FACTOR (Blue Key, MHz). | • This special function configures the Modulation Analyzer to use manual cal factors with the reference cal factor from the table as the manual entry. To re-enter the Automatic Cal Factor mode, select AUTOMATIC OPERATION or 37.0 SPCL.  
• Can be keyed only after selecting RF POWER. |
| 37.6 | Prepares to recall the next frequency/cal-factor pair from the table.  
Procedure: To display the frequency, select: 37.6 SPCL, DISPLAY FREQ (Blue Key, kHz).  
To display the cal factor, select: % CAL FACTOR (Blue Key, MHz).  
37.6 SPCL sequentially accesses frequency/cal-factor pairs. (See example in this section.) | • The table in memory is accessed sequentially (the lowest frequency accessed first). To access the lowest frequency in the table, select 37.5 SPCL before selecting 37.6 SPCL.  
• This special function configures the Modulation Analyzer to use manual cal factors with the cal factor recalled last from the table as the manual entry. To re-enter the Automatic Cal Factor mode, select AUTOMATIC OPERATION, then reselect RF POWER.  
• An attempt to read beyond the end of the table results in Error 26. |
| 37.9 | Clears the table of cal factors from memory. To enter a manual cal factor, use 37.1 SPCL. To enter a new table of calibration factors, use 37.3 SPCL. | • Displays Error 15 if automatic cal factors were being used.  
• Can be keyed from any Measurement mode. |
Additional Recommendations

- Re-calibrate the sensor when ambient conditions change or approximately every eight hours.
- Whenever the source frequency is changed, either select the new frequency manually (in MHz) or select FREQ to let the instrument automatically tune to the signal, then re-enter the RF Power measurement mode. Also, if the tuned frequency moves more that ±5 kHz from the frequency at which the power sensor reference was taken, the instrument must be retuned.
- Use the table on the following page, “Summary of Special Function 37” for a quick overview of all the codes that manipulate the RF power cal factors.

HP-IB PROGRAM CODES

% CAL FACTOR = CF  Hz = HZ  RF POWER = M4
CALIBRATE on = C1  LIN results = LN  SAVE CAL = SC
CALIBRATE off = C0  LOG results = LG  WATTS Units = WT
DISPLAY FREQ = FR  MHz = MZ  ZERO = ZR

MEASUREMENT TECHNIQUE

The RF Power Measurement

The power sensor produces a small dc voltage which is proportional to the power dissipated in the sensor’s input load. The dc voltage is then converted to ac, amplified, and converted back to dc. The Modulation Analyzer’s internal dc voltmeter measures the voltage and displays the reading in terms of power.

Five ranges of amplification are used to encompass the power sensor’s wide dynamic range. Special Function 10 permits manual selection of the five ranges: Range 1 (10.1 SPCL) has the most amplification (the most sensitivity), while Range 5 (10.5 SPCL) has the least amplification (the least sensitivity). The ranges are not specified in terms of absolute power because the sensor type determines the sensitivity.

The chopper in the power sensor converts the dc voltage (generated by the power sensing element) to a 220 Hz, chopped, ac signal. The ac signal is then amplified and rectified by a synchronous detector whose configuration alternates between a non-inverting and an inverting amplifier in step with the chopper. (The 220 Hz Multivibrator is the source for both chopping signals.) The result is a rechopped, dc level proportional to the dc output of the RF power sensing element of the power sensor. This chopping and recching method reduces the power meter’s susceptibility to dc drift and noise.

The dc level from the Synchronous Detector is filtered, to reduce noise then measured by the Voltmeter. On the more sensitive ranges, filtering is increased to smooth out the large noise component on the signal and thus stabilize the displayed reading.

RF Power Calibration

With the external power sensor properly connected to the Modulation Analyzer, and the sensor’s RF input connected to the CALIBRATION RF POWER OUTPUT, calibration begins by first determining the sensor type. (See the Simplified Block Diagram of RF Power Calibration.) A switch at the input of the Voltmeter connects the power sensor’s resistor to the Voltmeter. The voltage across the resistor indicates, to the Modulation Analyzer, the type of power sensor being used. UNCAL and RECAL annunciators are displayed if the sensor type differs from that used in a previous calibration.

When the ZERO key is pressed, the internal controller sends out a signal to the sensor module to switch out the RF input to the power sensor and directs the power meter to make a power
the calibrator output, the instrument will not zero properly.) The controller uses the zeroing digital-to-analog converter (DAC) in the power meter to output a dc voltage to cancel any dc offset that may be present at the power sensor. The zeroing process persists until the reading is zero, which may take several seconds to complete.

**RF Power Block Diagram**

**Simplified Block Diagram of RF Power Calibration**
When CALIBRATE is selected, the power reference oscillator outputs a calibrated, 1 mW signal at 50 MHz. When SAVE CAL is selected, the controller equates the output from the power meter to 1 mW.

The calibration procedure allows the instrument to set the power-measurement transfer function so the displayed power correctly represents the actual power. This procedure can be visualized as a process that adjusts the intercept and slope of the sensor's transfer function. The ZERO key sets the zero crossing (intercept), and the SAVE CAL key sets the gain (slope). (See the following figure.) The displayed power is given by the equation:

\[ P_{\text{dis}} = mP_{\text{act}} + b \]

where;

- \( P_{\text{dis}} \) is the Displayed Power,
- \( P_{\text{act}} \) is the Actual Power,
- \( b \) is the zero crossing, and
- \( m \) is the slope.

The calibration routine forces \( b = 0 \) and \( m = 1 \).

The following example shows the different responses that occur during calibration:

![Diagram showing the relationship between displayed and actual power before and after calibration adjustments](image)

Minor adjustments in the slope are made by the controller, based on the calibration factors, to correct for variations in the power sensor’s sensitivity due to frequency and mismatch.
COMMENTS

Reasons to Recalibrate

Any time the power-sensor type is changed (for example, from an HP 8482A to an HP 8484A), and RF POWER is selected, the Modulation Analyzer displays the need for recalibration by lighting the RECAL annunciator.

Any time power sensors of the same type are exchanged (for example, from one HP 11722A to another), and RF POWER is selected, the Modulation Analyzer DOES NOT recognize the need for recalibration. When in doubt about whether the calibration factors match the power sensor, use Special Function 37 to display the calibration factors as described in Procedure step #4 in this operating instruction.

Calibration information is retained in the Modulation Analyzer’s non-volatile memory even when the Modulation Analyzer is disconnected from its power source.

Finer Resolution for dB Measurements

Special Function 32.1 enables a resolution better than 0.004 dB. For audio frequency measurements, this special function enables a resolution of 0.1 Hz for frequencies from 100 to 250 kHz instead of the normally displayed resolution of 1 Hz. The selection of Special Function 32.0 or 32.1 is maintained through instrument power down.

32.0 Power is displayed with the normal measurement resolution of 0.01 dB.

32.1 Power is displayed with a measurement resolution better than 0.004 dB.

32.2 Displays 0 if the normal measurement resolution is enabled (32.0 SPCL) and displays 1 if a finer resolution is enabled (32.1).

Error 15

Error 15 is displayed until all necessary cal factor entries are made. Two calibration factors must be available for the Modulation Analyzer to make RF power measurements; a reference calibration factor, and a calibration factor at the signal frequency (entered manually or derived automatically from the Automatic Calibration Factor table). Also, if RF power measurements are attempted at frequencies higher or lower than any frequency in the table, interpolation is not possible and Error 15 is displayed.

---

2 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
A Second Cal-Factor Table for High-Frequency Measurements

A second table having up to 22 pairs of frequency/cal-factor pairs (plus a reference cal factor), is available for use with an external down-converter in the Frequency Offset mode. (Refer to Frequency Offset Control on page 3-225 for more information about this mode.)

When measuring power levels at high frequencies using a high-frequency power sensor or sensor module (such as the HP 11792A), enter the reference cal factor as an entry in the table at 50 MHz. If this frequency/cal factor pair is not entered, the instrument will not measure power at frequencies less than the lowest frequency entered in the cal factor table (2 GHz in the case of the HP 11792A).

Storing of Calibration Factor Tables

The Store/Recall function cannot store a cal-factor table. However, to avoid re-entering tables when frequent interchanging of power sensors is necessary, either use Manual Calibration Factors, or use the second table for the second power sensor. Select 27.3 SPCL and use 0 Hz as the external, Local Oscillator (LO) value. (Refer to Frequency Offset Control on page 3-225 for a procedure on entering an external LO value.)

These two Automatic Calibration Factor tables are retained in the instrument's non-volatile memory for use in all subsequent RF power measurements. Every time you use the second table, you must enter the external LO value.

User-Built Sensor Module

Any compatible power sensor can be configured as a sensor module using an external RF switch wired to the remote control connectors on the Modulation Analyzer's rear panel. (Refer to Remote Control RF Switch on page 3-107.)

Calibration Factor Resolution

Calibration factors have a resolution of 0.1%.

HP-IB: Interaction Between Calibration On and Zero

C0 aborts ZR, but when ZR is timed out, C1 is not aborted.

HP-IB: Using Save Cal

When calibrating the Modulation Analyzer over HP-IB, use T3 settling time code between the Calibrate and Save Cal codes. For example:

C1T3SC

Input/Output Status

MODULATION OUTPUT/AUDIO INPUT is disabled during RF power measurements.

Relative Measurements

If RF power is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Source Impedance

All measurement units assume a source impedance of 50Ω.
Power Measurements Alter Some Instrument States

The instrument exits the automatic tuning mode when the RF Power function is selected. The RF, LO, and IF sections are inactive since power is being measured at the external sensor.

Reference Cal Factor Not Affected by Changing the Cal Factor Mode

The SAVE CAL key, used in conjunction with RF Power Calibration, scales subsequent RF power measurements to the 1 mW RF Power Reference and saves the Scaling Factor in non-volatile memory. Changing the calibration factor mode does not change the reference calibration factor in use; for example, if the Modulation Analyzer is calibrated from the manual cal factor mode and then the Automatic Cal Factor mode is selected, the instrument will continue to use the manually-entered reference calibration factor until another SAVE CAL operation is initiated from the Automatic Calibration Factor mode.

Manual Cal Factors

Manual Cal Factors are not frequency selective; that is, as frequency is changed, the instrument will continue to use the calibration factor entered last. To obtain accurate measurements when using Manual Cal Factors, a new calibration factor should be entered each time the frequency is changed.

The Manual Calibration Factor is not retained in the Modulation Analyzer's non-volatile memory and therefore, must be re-entered after AUTOMATIC OPERATION or INSTR PRESET is selected.
RF Power Calibration Factor Entry Example Program

DESCRIPTION

The program list can be used to enter the RF power calibration factor (cal factor) table using an HP series 200 controller loaded with BASIC 3.0. (Cal factors are entered and stored in an internal table in the Modulation Analyzer's non-volatile memory—refer to RF Power.) It might be useful to use this program to enter the cal factor table rather than entering the cal factors manually.

You may want to modify this program. For example, to increase the number of cal factors that can be entered into the table, change program lines 220, 300, and 500 to specify to 16 rather than to 10. When running this program, softkeys are set up with the following labels:

- **Address**
  - Allows you to enter the HP-IB address of the Modulation Analyzer.

- **Display Table**
  - Displays the table of cal factors just entered. These are not necessarily the cal factors being used by the Modulation Analyzer.

- **Enter Table**
  - Enables you to enter individual cal factors into the cal factor table.

- **Read Cal**
  - Displays the calibration factor table currently being used by the Modulation Analyzer.

- **Send**
  - Loads the calibration factor table into the Modulation Analyzer that was entered with **Enter Table**.

PROCEDURE

Enter the program into an HP series 200 controller and connect the Modulation Analyzer (via HP-IB) to the controller. Connect the power sensor or sensor module to the Modulation Analyzer's SENSOR input. (The power sensor cable need not be connected to the source at this time.)

Follow the steps below to use the program. (Note that words that have brackets around them like this:<RUN>, are keys on the controller. Words in boxes like this: [Address], are softkeys displayed on the controller's screen.)

1. Select <Run>.

2. Select softkey, [Address] and enter the three-digit code that comprises the controller's select code (for example, 7) and the Modulation Analyzer's address (for example, 14). (Display the Modulation Analyzer's address by selecting BUS ADRS—Blue Key, LOCAL—on the Modulation Analyzer.) For these examples, you would type in:

   **7 1 4 <ENTER>**

3. If you want to display the cal factors currently being used by the measuring receiver, go to step 7.
4. Enter the new frequency/cal factor pairs by selecting  

   a. The controller will prompt:

   "New Cal Factor for REF position cal factor?"
   Enter the reference calibration factor. For example, enter 100% as:

   1 0 0 <ENTER>  

   b. The controller will prompt:

   "New Frequency for number '1' cal factor?"
   Enter the frequency (in MHz) for the first frequency/cal factor pair. For example, enter 100 kHz as:

   .1 <ENTER>  

c. The controller will prompt:

   "New Cal Factor for number '1' frequency?"
   Enter the cal factor for the first frequency/cal factor pair, for example, enter 99.0% as:

   9 9 . 0 <ENTER>  

d. Continue entering the nine other frequency/cal factor pairs until the table is complete.

Note that selecting ENTER as a response to a prompt without specifying a value will automatically select the value currently in the table.

5. Select Display Table to see the cal factors that you have entered.

6. Select Send to put those cal factors into the cal factor table in the Modulation Analyzer.

7. To display the cal factors currently used by the Modulation Analyzer, select Read Cal.

   The controller will query the Modulation Analyzer and then display a list of frequency/cal-factor pairs currently in the table. The cal factors are listed in the format:

   

   

   

   

   

   

   The first column lists each frequency (in MHz) of the frequency/cal factor pair. The second column lists each cal factor (in %) of the frequency/cal factor pair. (The first frequency/cal factor pair listed is the reference cal factor that is measured at 50 MHz. This frequency cannot be changed.) To enter new frequency/cal factor pairs, go to step 4.

RF Level

FUNCTIONS
Special Function 35 (RF Level)

DESCRIPTION
The RF Level function enables the Modulation Analyzer to measure and display the peak, RF power. RF level measurements are initiated with Special Function 35 or with the RF POWER key when there is no sensor at the Modulation Analyzer’s SENSOR input.

RF level measurements are not calibrated, so they are not as accurate as measurements made with an external power sensor as with RF Power measurements. (Refer to RF Power on page 3-71.)

PROCEDURE
To make a broadband RF power measurement with an RF cable connected from the signal source to RF INPUT (rather than a power sensor connection), select RF POWER.

To make the measurement with the power sensor connected, key in 35.0 SPCL.

HP-IB PROGRAM CODES
LIN = LN
LOG = LG
RF POWER = M4
SPCL = SP

MEASUREMENT TECHNIQUE
The broadband RF power at RF INPUT is detected by an RF peak detector. The output of the detector is measured and displayed.

When RF Level is selected, the Modulation Analyzer sets its RF input attenuation to 50 dB to minimize SWR. Any manual setting of RF input attenuation (Special Function 1) is overridden.

RF Level Measurement Block Diagram
COMMENTS

Input/Output Status

MODULATION OUTPUT/AUDIO INPUT is turned off during this measurement. However, AM OUTPUT and FM OUTPUT (rear panel) remain active but uncalibrated. The tuning of the instrument remains unchanged.

Relative Measurements

If RF level is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Measuring RF Level on Signals with AM

If the RF input signal has AM, the peak envelope power is measured.

Previous Input High-Pass Filter Selection

The input high-pass filter (Special Function 3) remains inserted if previously selected.

Error 06

The maximum allowable input level is 1W into 50Ω. Input levels greater than 1W cause the overpower relay to open and the display to show Error 06. To reset the relay, remove the input signal and select any measurement key.
Recorder Output

FUNCTIONS

Special Functions 49 and 50 (Display Internal Voltages)

[CAUTION]

Voltages greater than 10 Vdc applied to the RECORDER OUTPUT could cause damage to the internal circuitry.

DESCRIPTION

The RECORDER OUTPUT makes available the voltage that is being read by the instrument's internal dc voltmeter. Accuracy can be improved for some measurements by connecting to the RECORDER OUTPUT a dc voltmeter that has greater accuracy, linearity, offset, and resolution than the internal voltmeter. This procedure significantly improves the accuracy of the RF Power measurement.

In normal operation, the internal voltmeter is constantly taking readings at various points throughout the instrument as part of its measurement process. The signal at the RECORDER OUTPUT then, is a random series of pulses of varying level. When Special Function 49 or 50 is not enabled, the RECORDER OUTPUT is useful mostly as a troubleshooting aid.

However, Special Functions 49 and 50 can set the internal voltmeter to suspend normal operation and to measure one input only. The voltmeter's input is displayed and delivered to the RECORDER OUTPUT. This feature has two general applications: data logging (for example on a stripchart recorder) and accuracy improvement.

Special Functions 49 and 50 are Service Special Functions which are documented more fully in Section 8 of the Service Manual. Use the following partial list of Special Functions to “freeze” the instrument (no ranging, retuning, etc.) and deliver to the RECORDER OUTPUT a dc voltage equal to the level being read by the internal dc voltmeter:

</table>

* A is Gold Shift, 0; B is Gold Shift, 1; D is Gold Shift, 3; E is Gold Shift, 4; and F is Gold Shift, 5; "B" is displayed as "b" and "D" as "d". For HP-IB programming use "X" in place of the Gold Shift Key.

** For this Special Function, proceed with Special Function 0.212. Ignore the display after keying in Special Function 0.212.

### Procedure

To do analog data logging with the Modulation Analyzer:

1. Connect the logging device to the RECORDER OUTPUT.
2. Select the desired measurement. Since the instrument will not be safeguarded (no ranging, retuning, error messages, etc), be sure the instrument is set up properly for worst-case expected signal conditions.
3. Key in the appropriate special function using the preceding table as a guide.

### Note

The measurement unit is volts. Readings in excess of 4 are not valid. Most measurements satisfy calibration requirements since the measured voltage is directly proportional to the normal measurement display. For example, if a normal FM reading is 350 kHz, a RECORDER OUTPUT of 350, using Special Function 490A, corresponds to 350 kHz peak FM deviation.

For data logging RF power, use the following procedure.

To increase accuracy of RF Power measurements:

1. Connect an accurate dc voltmeter to the RECORDER OUTPUT. The voltmeter should have at least a 1 MΩ input impedance. Let the instruments warm up for at least one-half hour.
2. Connect a compatible power sensor or sensor module to the SENSOR input. Connect the power sensor's input to the CALIBRATION RF POWER OUTPUT.
3. Select RF POWER, then ZERO. Wait for the ZERO key light to go out.
4. Key in the following Special Functions in order and record the external dc voltmeter readings. (The "S" in the Special Function code is the Gold Shift key. After keying in S 5, an "F" is displayed.)
<table>
<thead>
<tr>
<th>Special Function</th>
<th>Variable Name</th>
<th>Voltmeter Reading in V</th>
</tr>
</thead>
<tbody>
<tr>
<td>103, 0212, 490 S 5</td>
<td>$V_{z3}, V_{z4}, V_{z5}$</td>
<td></td>
</tr>
<tr>
<td>102, 0212, 490 S 5</td>
<td>$V_{z2}$</td>
<td></td>
</tr>
<tr>
<td>101, 0212, 490 S 5</td>
<td>$V_{z1}$</td>
<td></td>
</tr>
</tbody>
</table>

NOTE

For best accuracy on the most sensitive range (range 1), the zero offset voltage ($V_{z1}$) should be averaged for many voltmeter measurement cycles. This is most easily done via a programmable voltmeter under HP-IB control.

5. Key in 10.0 SPCL then CALIBRATE. Key in 49.0, S, 5, SPCL. Record the voltmeter reading ($V_c$). Select SAVE CAL (Blue Key and CALIBRATE key) to calibrate the Modulation Analyzer's display. The display should read 1 mW.

$$V_c = \underline{\text{__________}} \text{V}$$

6. Select SPCL twice. Record the least-significant digit (the tenth digit) on the display ($R_c$). (This digit indicates the RF Power range for the calibration.)

$$R_c = \underline{\text{__________}}$$

7. Select AUTOMATIC OPERATION. Select CALIBRATE to turn off the Recorder Output Mode.

8. Connect the signal source to the power sensor’s input. Allow the Modulation Analyzer to make a normal RF power measurement.

9. Key in 0.212 SPCL Key in 49.0, S, 5, SPCL and record the voltmeter reading ($V_p$).

$$V_p = \underline{\text{__________}} \text{V}$$

10. Select SPCL twice. Record the least-significant digit (the tenth digit) on the display ($R_p$). (This digit indicates the RF Power range.)

$$R_p = \underline{\text{__________}}$$

11. Compute the RF power ($P$, in mW) from the following formula:

$$P = \frac{C F_c}{C F_p} \times \frac{V_p - V_{zR_p}}{V_c - V_{zR_c}} \times 10(R_p - R_c)$$

where

$C F_c$ is the reference (50 MHz) calibration factor from the chart on the power sensor;

$C F_p$ is the calibration factor at the signal frequency from the chart on the power sensor;

$V_{zR_c}$ is the voltage from step 4 for range $R_c$;

$V_{zR_p}$ is the voltage from step 4 for range $R_p$.

12. Begin subsequent RF power measurements at step 2 as long as the results of step 4 exhibit drift; otherwise, begin at step 9.

COMMENTS

More Information

For further details on Special Functions 49 and 50, refer to Service Special Functions in Section 8.

Internal Voltmeter Offset

The RF power circuits do not zero to 0V. Instead they “zero” to between 0.5V and 0.8V which permits the internal dc voltmeter to operate over its most linear range. The internal controller subtracts this offset from subsequent power readings.
Tuned RF Level

FUNCTIONS
TUNED RF LEVEL

DESCRIPTION
The Tuned RF Level function enables the Modulation Analyzer to measure the peak level of the down-converted RF input falling in the IF. The term “peak level” refers to the fact that a peak-responding IF detector is used to measure the signal level. The internal controller converts this level to average power and displays the result. (See the block diagram in “MEASUREMENT TECHNIQUE”.) The Tuned RF Level function is not calibrated, and so it is not as accurate or sensitive as the RF Power function. The peak Tuned RF Level function enables the instrument to measure the level of frequencies that are drifting, or to determine flatness as a function of carrier frequency. This function is more sensitive than the RF Level (Special Function 35) measurement mode.

PROCEDURE
To make a tuned RF level measurement, first tune the instrument to the input signal by selecting AUTOMATIC OPERATION. Select TUNED RF LEVEL (Shift, RF POWER).

HP-IB PROGRAM CODES
LIN results = LN
LOG results = LG
VOLTS units = VL
mV units = MV
uV units = UV
WATTS units = WT

MEASUREMENT TECHNIQUE
When the Modulation Analyzer is tuned, all the power falling within the IF bandpass filter is amplified and peak detected. The detected power is then measured by the voltmeter and displayed in the selected measurement units.

Tuned RF Level Measurement Block Diagram
COMMENTS

Input/Output Status

When the tuned RF level measurement is selected, MODULATION OUTPUT/AUDIO INPUT is blanked. AM OUTPUT and FM OUTPUT (rear panel) remain active during this measurement.

Relative Measurements

If the tuned RF level is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)
IF Level

FUNCTIONS

IF LEVEL

DESCRIPTION

The signal level in the Modulation Analyzer's IF can be measured and displayed as a percent of the optimum level. An IF level display of 100% indicates sufficient signal strength to guarantee accurate modulation measurements. AM accuracy is directly affected by the IF level. FM and ΦM accuracy is affected only if the IF level is very low.

PROCEDURE

To display the IF level as a percent of optimum, select IF LEVEL (Shift, ΦM).

HP-IB PROGRAM CODE

IF LEVEL = S3

MEASUREMENT TECHNIQUE

Once the instrument is tuned and the IF Level function is selected, the automatic level control (ALC) loop of the AM Demodulator detects the average level of the IF. If the ALC loop is closed and there is sufficient IF signal available, the ALC loop automatically adjusts the IF gain within the loop to force the detected IF to equal the ALC reference. When the instrument is running in automatic operation, the input attenuation is adjusted to keep the IF level within range of the ALC loop.

In the IF Level measurement mode, the detected IF level is compared to the ALC reference and the ratio of the two levels is expressed as a ratio in %. If the ALC loop is closed and if there is sufficient IF level, the display will read 100%. If the ALC loop is open (Special Function 6.2) or if there is insufficient IF level, the display will not read 100%. If the IF level is too high the display will read greater than 100%. If the IF level is too low, the display will read less than 100%.

BLOCK DIAGRAM

IF Level Measurement Block Diagram
COMMENTS

Acceptable IF Level Display

An IF level display between 99.9% and 100.1% is considered acceptable for all measurements.

Input/Output Status

When IF LEVEL is selected, the output at MODULATION OUTPUT/AUDIO INPUT continues to output the demodulated signal corresponding to the last modulation measurement selected as indicated by the MODULATION OUTPUT annunciator. If the IF level is not 100%, the calibration of the output is directly affected for AM and degraded for FM and ΦM if the IF level is very low.

Relative Measurements

If IF level is to be displayed relative to a reference level, enter the ratio reference using the RATIO key. (Refer to Ratio on page 3–215.)

IF Levels Less Than 100%

Error 03 (input circuits underdriven) is generated whenever the IF level is less than 100% unless the ALC loop is open. Override this Error Message using Special Function 8. (Refer to Error Message Disable Control on page 3–233.)

AM Depth When IF Level is Insufficient

When operating with the AM ALC loop open or when the IF level is insufficient, the displayed AM is proportional to the actual AM depth, and the displayed IF level is proportional to the average carrier level. The actual AM depth can be computed as the ratio of the two readings with the following formula:

\[
AM\ in\ % = \frac{demodulated\ ac}{average\ carrier\ level} \times 100\% = \frac{displayed\ AM}{displayed\ IF\ level} \times 100\%
\]

The Ratio feature can be used to simplify this calculation: First, measure the IF level, then press the AM key and enter the IF level on the numeric keys. Then press the RATIO key. AM is now displayed although the IF level is not optimum.

Guidelines for Measurements when AM ALC is Off

In most circumstances, when the AM ALC is off (loop open), use IF levels greater than or equal to 100% for FM measurements and less than or equal to 100% for AM measurements.
Selective Power Measurements (Option 030)

FUNCTIONS
Special Functions 23 (External LO) and 24 (Selective Power Measurements)

DESCRIPTION
The Series 030, Selective Power Measurement Options enable the Modulation Analyzer to measure adjacent-channel power and single-sideband noise on continuous wave (CW) RF signals. Both measurements basically consist of tuning the instrument to the RF signal, measuring the IF level in the passband of a selected IF filter, then offsetting the signal onto the skirt of the IF filter and re-measuring the IF level. Offsetting the signal places a portion of the sideband noise of the carrier in the passband of the IF filter. The ratio of the out-of-band IF level to the in-band IF level is the desired measurement result (expressed in dB).

The measurement procedure requires that the operator step through a sequence of special functions and increment either the local oscillator (LO) or the signal source. For RF signal frequencies above 300 MHz, an external LO is recommended for greatest sensitivity and accuracy. Special Function 23 switches the LO between internal and external. The external LO connects to a rear-panel connector. (Since Option Series 030 provide rear-panel LO input and output connectors, Option 003 is not available in conjunction with the 030 Series Options.)

The 030 Series Options include the choice of two IF bandpass filters installed. The bandwidths of these IF filters match the requirements of specific industry standards for measuring adjacent-channel power. The following table lists the optional filters and their bandwidths.

<table>
<thead>
<tr>
<th>Filters</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.5 kHz Adjacent Channel Filter</td>
<td>Option 032</td>
</tr>
<tr>
<td>25 kHz Adjacent Channel Filter</td>
<td>Option 033</td>
</tr>
<tr>
<td>30 kHz (Cellular Radio) Filter</td>
<td>Option 035</td>
</tr>
<tr>
<td>Carrier Noise Filter</td>
<td>Option 037</td>
</tr>
</tbody>
</table>

All selective power measurements consist of three processes. The first two are identical for either adjacent channel power or single-sideband noise measurements. However, the third step is different depending on the measurement being made:

1. Setting up the LO:
   Put the Modulation Analyzer in its selective power measurement mode. If using an external LO, enter an LO value into the Modulation Analyzer that is offset 455 kHz from the incoming signal. If using the Modulation Analyzer’s internal LO, just tune to the input signal.

2. Setting the reference:
   Measure the voltage reference and set that reference to be 0 dB. (Adjust the LO frequency to ensure that the peak value is being measured.) Then measure the peak voltage reference and set it to be 0 dB.

3a. Measuring the adjacent channel power:
   Tune the LO to the 6 dB point of the filter and move the LO the spacing required for the appropriate adjacent channel filter.

3b. Measuring the single-sideband noise:
   Choose whether to display the data as total power in the 2.5 kHz filter bandwidth or as dBC in a 1 Hz bandwidth. Tune the Modulation Analyzer (or the external LO) to the offset frequency desired and measure the noise.
PROCEDURE

The following procedures are examples of typical measurement applications. These procedures describe the steps for measuring adjacent-channel power and single-sideband noise.

Adjacent Channel Power Measurements

Two procedures are available. The first procedure measures the lower adjacent channel power. The second procedure measures the upper adjacent channel power.

To Measure the Lower Adjacent Channel Power

Setting Up the LO

1. Tune to the input frequency. (Selecting the FREQ key automatically tunes the Modulation Analyzer to the input frequency. Keying in the input frequency value (in MHz) followed by the MHz key manually tunes the Modulation Analyzer to the frequency value keyed in. For more information about tuning, refer to RF Frequency Tuning.)

2. Press the MHz key to manually tune and center the IF.

3. Select 24.0 SPCL to enter the Selective Power Measurement mode.

4. Select whether an external LO or the Modulation Analyzer's internal LO will be used. If the internal LO will be used, go to step 7. If an external LO will be used, connect the LO signal source to the LO INPUT connector on the rear panel of the Modulation Analyzer. (More information about the LO INPUT is available in LO Input and LO Output.)

5. Set the external LO source frequency to 455 kHz greater than the input frequency and its amplitude to 0 dBm.

6. Key in 23.1 SPCL to set the LO to external.

Setting the Reference

7. Select 24.1 SPCL to establish the IF reference value (in volts).

8. Select 24.2 SPCL to set the reference to 0 dB.

9. Adjust the LO frequency until the maximum value is displayed. The Modulation Analyzer's automatic tuning capability measures an IF value close to the peak, but the internal circuitry does not specifically check for a peak. This step enables you to fine tune to the peak of the signal.
   a. If using an external LO, step the LO frequency in small increments until the peak value is measured.
   b. If using the internal LO, set the desired increment value (in kHz) and step the LO using the kHz and kHz keys until the maximum value is displayed.

10. Reselect 24.1 SPCL to establish the IF reference value (since that value has now been peaked).

11. Reselect 24.2 SPCL to set the reference to 0 dB.

Measuring the Lower Adjacent Channel Power

12. Decrease the LO frequency value until −6 dB is displayed. Note the frequency difference between the source and the LO. This frequency difference is relative to the 6 dB corner of the IF bandpass filter. (Once the 6 dB corner frequency has been determined, the corner need not be remeasured when new measurements are made with that filter.)
13. Decrease the LO frequency by an offset of either 8.25 kHz, 13 kHz, or 17 kHz depending on the adjacent channel being measured (refer to the table below).

<table>
<thead>
<tr>
<th>Channel Spacing in kHz</th>
<th>Displacement of the 6 dB Point per CEPT (in kHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.5 kHz</td>
<td>8.25 kHz</td>
</tr>
<tr>
<td>20 kHz</td>
<td>13 kHz</td>
</tr>
<tr>
<td>25 kHz</td>
<td>17 kHz</td>
</tr>
</tbody>
</table>

14. The value displayed is the adjacent channel power measurement result.

**To Measure the Upper Adjacent Channel Power**

**Setting Up the LO**

1. Tune to the input frequency. (Selecting the FREQ key automatically tunes the Modulation Analyzer to the input frequency. Keying in the input frequency value (in MHz) followed by the MHz key manually tunes the Modulation Analyzer to the frequency value keyed in. For more information about tuning, refer to RF Frequency Tuning.)

2. Press the MHz key to manually tune and center the IF.

3. Select 24.0 SPCL to enter the Selective Power Measurement mode.

4. Select whether an external LO or the Modulation Analyzer's internal LO will be used. If the internal LO will be used, go to step 7. If an external LO will be used, connect the LO signal source to the LO INPUT connector on the rear panel of the Modulation Analyzer. (More information about the LO INPUT is available in LO Input and LO Output.)

5. Set the external LO source frequency to 455 kHz less than the input frequency and its amplitude to 0 dBm.
   a. If using the internal LO, on the Modulation Analyzer select 910 ▼ kHz. This tunes the Modulation Analyzer to the image frequency of the LO. At this time, the RF frequency display will not match the input frequency value.

6. Key in 23.1 SPCL to set the LO to external.

**Setting the Reference**

7. Select 24.1 SPCL to establish the IF reference value (in volts).

8. Select 24.2 SPCL to set the reference to 0 dB.

9. Adjust the LO frequency until the maximum value is displayed. The Modulation Analyzer's automatic tuning capability measures an IF value close to the peak, but the internal circuitry does not specifically check for a peak. This step enables you to fine tune to the peak of the signal.
   a. If using an external LO, step the LO frequency in small increments until the peak value is measured.
   b. If using the internal LO, set the desired increment value (in kHz) and step the LO using the ↑ kHz and ↓ kHz keys until the maximum value is displayed.

10. Reselect 24.1 SPCL to establish the IF reference value (since that value has now been peaked).

11. Reselect 24.2 SPCL to set the reference to 0 dB.

**Measuring the Upper Adjacent Channel Power**

12. Increase the LO frequency value until −6 dB is displayed. Note the frequency difference between the source and the LO. This frequency difference is relative to the 6 dB corner of the IF bandpass filter. (Once the 6 dB corner frequency has been determined, the corner need not be remeasured when new measurements are made with that filter.)
13. Increase the LO frequency by an offset of either 8.25 kHz, 13 kHz or 17 kHz depending on the adjacent channel being measured (refer to the table below).

<table>
<thead>
<tr>
<th>Channel Spacing in kHz</th>
<th>Displacement of the 6 dB Point per CEPT (in kHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.5 kHz</td>
<td>8.25 kHz</td>
</tr>
<tr>
<td>20 kHz</td>
<td>13 kHz</td>
</tr>
<tr>
<td>25 kHz</td>
<td>17 kHz</td>
</tr>
</tbody>
</table>

14. The value displayed is the adjacent channel power measurement result.

**Single-Sideband Noise Measurements**

Use this procedure only when Option 037 has been installed.

**Setting Up the LO**

1. Tune to the input frequency. (Selecting the FREQ key automatically tunes the Modulation Analyzer to the input frequency. Keying in the input frequency value (in MHz) followed by the MHz key manually tunes the Modulation Analyzer to the frequency value keyed in. For more information about tuning, refer to RF Frequency Tuning.)
2. Press the MHz key to manually tune and center the IF.
3. Select 24.0 SPCL to enter the Selective Power Measurement mode.
4. Select whether an external LO or the Modulation Analyzer’s internal LO will be used. If the internal LO will be used, go to step 7. If an external LO will be used, connect the LO signal source to the LO INPUT connector on the rear panel of the Modulation Analyzer. (More information about the LO INPUT is available in LO Input and LO Output.)
5. Set the external LO source frequency to 455 kHz greater than the input frequency and its amplitude to 0 dBm.
6. Key in 23.1 SPCL to set the LO to external.

**Setting the Reference**

7. Select 24.5 SPCL to establish the IF reference value (in volts).
8. Select 24.6 SPCL to set the reference to 0 dB.
9. Adjust the LO frequency until the maximum value is displayed. The Modulation Analyzer’s automatic tuning capability measures an IF value close to the peak, but the internal circuitry does not specifically check for a peak. This step enables you to fine tune to the peak of the signal.
   a. If using an external LO, step the LO frequency in small increments until the peak value is measured.
   b. If using the internal LO, set the desired increment value (in kHz) and step the LO using the up kHz and down kHz keys until the maximum value is displayed.
10. Reselect 24.5 SPCL to establish the IF reference value (since that value has now been peaked).
11. Reselect 24.6 SPCL to set the reference to 0 dB.

**Making the Single-Sideband Noise Measurement**

12. If you want the measurement to be displayed as total power in the 2.5 kHz bandwidth, go to the next step. If you want the measurement to be normalized to 1 Hz, select 24.7 SPCL.
13. Adjust the LO frequency by the desired offset to display the noise value. The value displayed is the single-sideband noise measurement result.
Additional Special Functions for Single-Sideband Noise

These special functions enable you to change and display the noise measurement bandwidth. The noise measurement bandwidth is measured and entered at the factory and probably does not need to be remeasured unless operating conditions for the Modulation Analyzer change radically.

1. Special Function 24.8 Changes the noise measurement bandwidth used in single-sideband noise measurements. The value entered (in units of MHz) must be between 100 Hz and 20 kHz (0.0001 and 0.02 MHz). To enter a noise measurement bandwidth key in 24.8 SPCL then key in the bandwidth expressed in MHz and press the MHz key. This factor is stored in non-volatile memory. Determination of the noise measurement bandwidth is usually done by numerical integration of the IF filter response.

2. Special Function 24.9 Displays the value of the noise measurement bandwidth used in conjunction with Special Function 24.7. The displayed value times out after a few seconds.

MEASUREMENT TECHNIQUE

The Series 030 Options add more IF signal processing circuitry to the Modulation Analyzer including programmable IF amplifiers and filters and a true rms IF detector. (Refer to the Selective Power Measurement Option simplified block diagram.)
Initializing

The Modulation Analyzer must be set up for the first part of the measurement which establishes the IF reference level. This is most easily done by keying in Special Function 24.0 which:

- holds the RF input attenuator;
- sets the IF to 455 kHz, retunes the LO to accommodate the 455 kHz IF, and sets the LO to the manual-tune, low-noise mode;
- inserts the RF Input High-Pass Filter (which limits the lowest RF input frequency to 10 MHz but filters any low-frequency RF input signals from interfering with the measurement); and
- disables Error Messages 01 through 04.

The Measurement Sequence

The first step in the measurement sequence is to tune the LO to the RF input signal to center the IF in the IF filter passband. Refer to (a.) in the figure “Signal Tuning Illustrating Frequency Offsetting”. After the instrument is properly tuned the IF (in-band) level is measured with the IF RMS Detector. The in-band IF level is defined as a ratio reference.

Next the frequency is offset either by tuning the RF input signal (if this is possible) or by tuning the LO as illustrated in (b.) and (c.) of the same figure. Note that tuning is in opposite directions. If it is desired to offset the IF to the upper skirt of the IF filter, the RF frequency must be decreased or the LO frequency increased.

After the signal is offset, a second (out-of-band) IF level measurement is made with the same IF RMS Detector. Since the IF level has decreased considerably, the IF gain is adjusted to bring the IF level within the optimum range of the IF RMS Detector. The ratio of the out-of-band IF level to the in-band level is computed and displayed. Out-of-band IF signal appears in the IF passband because of

- sideband noise on the RF input signal,
- modulation sidebands on the RF input signal (if the signal is modulated),
- sideband noise on the LO, and
- the limited signal rejection in the stopband of the IF bandpass filter.

Since it is desired to measure only the first two contributions (that is, the contributions of only the RF input signal), care must be taken to choose the correct frequency offset, the proper LO, and the proper IF filter.
(a.) No Frequency Offset

(b.) Frequency Offset by Increasing RF Signal Frequency

(c.) Frequency Offset by Increasing LO Frequency

Signal Tuning Illustrating Frequency Offsetting
COMMENTS

Frequency Modes Possible During the Selective Power Measurement

During the selective power measurement, the instrument must be properly tuned to the signal and must be in one of the following RF Frequency measurement modes:

- RF Frequency (the FREQ key, HP-IB Code: M5),
- RF Frequency Error (the S, FREQ ERROR keys, HP-IB Code: S5),
- IF Frequency (Special Function 34, HP-IB Code: 34.0SP), or
- LO Frequency (Special Function 33, HP-IB Code: 33.0SP).

When To Use an External LO

A low-noise, external LO is recommended for RF input frequencies above 300 MHz. Also, an external LO can be selected for lower phase noise and finer resolution in its frequency steps.

When an external LO is used, the internal LO should be manually tuned to an arbitrary frequency (such as 100 MHz) to defeat automatic signal search. Refer to RF Frequency Tuning for tuning information. (Note that the 455 kHz IF will be used.)

Frequency Offsetting

The IF frequency can be offset by one of the following three methods:

- offsetting the RF input signal.
- offsetting the external LO, or
- offsetting the internal LO using the ↑ kHz or ↓ kHz keys.

An increase in the RF input signal moves the IF signal down the lower skirt of the IF bandpass filter. An increase in the LO frequency (either external or internal) moves the IF signal down the upper skirt. Refer to Measurement Technique for an illustration of this.

The measurement specification may require that the frequency offset be made from the 6 dB corner frequency of the IF bandpass filter.

Finding the IF Peak

For maximum accuracy, the frequency offset should be relative to the frequency at which the IF signal is peaked in the IF bandpass filter. (IF filter ripple can be as high as ±2 dB.) Automatic tuning brings the IF close to the peak, but the instrument controller does not specifically check for an IF peak. Finding the IF peak is most easily accomplished by tuning the RF input signal (if this is possible) or by tuning the external LO while Special Function 24.1, 24.3, or 24.5 is active. The RF input signal or external LO is tuned until the displayed IF voltage is at its peak. Finding the IF peak by incrementing the internal LO is similar, but the active special function must be re-entered after each frequency increment. Tuning requires a range of only a few kHz.

In all the measurements, you can tune the input signal instead of the LO. This is the easiest way if the source is tuneable. However, you must tune the source opposite to the direction you would tune the LO. For example, if you tune the LO down, you would tune the source up in frequency.
IF Output

**CAUTION**

Do not apply greater than 40 Vdc or greater than +15 dBm into the rear-panel IF OUTPUT connector.

**DESCRIPTION**

The rear-panel IF OUTPUT (a female BNC connector) provides a buffered output to enable monitoring of the Modulation Analyzer's IF signal. The ac-coupled signal ranges from 150 kHz to 2.5 MHz and normally varies in level from −27 to −3 dBm (into 50 ohms). The level variation depends on the RF input signal level, RF input attenuation setting, and the measurement selected.

The 3 dB bandwidth of the signal at IF OUTPUT is approximately 3 MHz when the instrument uses the wide, 2.5 MHz low-pass filter and approximately 200 kHz when the instrument uses the wide, 455 kHz bandpass filter.

At any particular input level and front-panel setting, the flatness of the IF OUTPUT, as input frequency varies, is typically within ±5%.

**BLOCK DIAGRAM**

![IF Output Block Diagram](image)

**COMMENTS**

**Use the Modulation Analyzer as a Down Converter**

The Modulation Analyzer can be used as a high-quality, automatically tuneable, down-converter. Use the IF OUTPUT as the down-converter’s output.

**Adjacent Spurious Signals**

Check for close-in spurious signals on the RF input by connecting a spectrum analyzer to IF OUTPUT. When connecting instruments such as counters to the IF OUTPUT, check that they do not inject spurious signals into the IF path. Spurious signals in the Modulation Analyzer’s IF may generate measurement error.
External Attenuation (dB)

FUNCTIONS

dB EXT ATTEN, Special Function 25 (External Attenuation dB)

DESCRIPTION

Level measurements can be scaled to correctly indicate the power at the input of an external attenuator or amplifier connected to the instrument.

Special Function 25.2 causes display of the value of the selected external dB attenuation or gain.

PROCEDURE

To enter external attenuation:

1. Select the keys corresponding to the magnitude of external attenuation or gain expressed in dB.

2. If the offset is gain rather than attenuation, designate the value as negative by selecting the Blue Key and minus-sign (−) key (the decimal key). No sign indication is necessary for entering attenuation.

3. Select dB EXT ATTEN (Blue Key, LOG/LIN).

To display the current offset in dB, key in 25.2 SPCL.

To exit external attenuation, select dB EXT ATTEN again.

To re-enter external attenuation, select dB EXT ATTEN again.

EXAMPLE

To account for an external 10 dB amplifier connected to the instrument:

<table>

</tr>
</tbody>
</table>

To display

Data 10 N1

Display
**HP-IB PROGRAM CODES**

- dB EXT ATTN off = N0
- dB EXT ATTN on = N1
- SPCL = SP

When the dB EXT ATTN key is pressed, the Modulation Analyzer displays subsequent level measurements using the entered dB offset.

**COMMENTS**

**Input/Output Status**

MODULATION OUTPUT/AUDIO INPUT is blanked during most level measurements.

**External Attenuation Value is Stored Through Other Measurement Selection**

If another Measurement mode is selected while the external attenuation function is enabled and a level Measurement mode is re-entered, the instrument automatically re-enters the external attenuation mode with the previous offset.
Remote Control RF Switch

DESCRIPTION

A compatible, external power sensor is required for making accurate, absolute RF power measurements. The Modulation Analyzer can be used with the following sensor configurations:

- A power sensor selected from the HP 8480 series sensors.
- A sensor module (such as the HP 11722A) that contains a power sensor, an RF switch, and an RF coaxial cable. The Modulation Analyzer controls the RF switch in the sensor module to automatically switch the RF input signal between the RF INPUT of the Modulation Analyzer and the power sensor as measurements require.
- A sensor module, built by the user, that includes a power sensor (from the HP 8480 series sensors), an RF cable, and an RF switch (such as the HP 33311 series or the HP 8761A). The rear-panel REMOTE CONTROL RF SWITCH outputs enable the Modulation Analyzer to automatically switch the RF input signal between the RF input of the Modulation Analyzer and the power sensor as measurements require.

NOTE

An HP 478A is a standard sensor but is not compatible with the Modulation Analyzer.

PROCEDURE

The following procedure provides a few guidelines for setting up and operating a remotely controlled sensor module.

Connect the RF switch, power sensor, RF cable, and Modulation Analyzer as shown in the BLOCK DIAGRAM. Do not connect a sensor module (such as the HP 11722A) to the SENSOR input if the rear-panel remote control switches are to be used with a user-built sensor module. The control lines are in parallel, and the internal switch drive circuits cannot drive both.

The remote outputs are capable of driving both 5V and 12V to 15V switch solenoids. The solenoids should be of a latching type, but they need not have automatic drive disconnect. Examples of compatible RF switches are the HP33311B, Option 011 (5V solenoid) or the HP 8761A (12V to 16V solenoid).

Proceed with selected measurements. This user-built module will enable the Modulation Analyzer to automatically switch between its inputs as measurements require.
REMOTE CONTROL Outputs are Exclusive to Compatible Switches

The rear-panel REMOTE CONTROL outputs are not intended as general-purpose switch drives. The output should only be used with compatible RF switches.

RF Input Frequency

FUNCTIONS
FREQ

DESCRIPTION
The Modulation Analyzer can measure RF input signals from 150 kHz to 1300 MHz. (Higher frequencies can be measured using an external mixer as described in Frequency Offset Control on page 3-225.)

To count input frequencies between 2.5 and 1300 MHz, the Modulation Analyzer uses heterodyning; to count input frequencies from 150 kHz to 2.5 MHz, it counts the input directly.

In most circumstances, when using manual tuning and when the approximate frequency is known, the instrument can count signals with power levels less than −60 dBm.

PROCEDURE
To make an input frequency measurement, first tune the instrument to the input signal (select AUTOMATIC OPERATION or refer to RF Frequency Tuning on page 3-115 to learn about more ways to tune the Modulation Analyzer.) Select FREQ.

Manual tuning will be necessary when measuring low-level signals (inputs less than −25 dBm from 150 kHz to 650 MHz or less than −20 dBm from 650 to 1300 MHz).

HP-IB PROGRAM CODE
FREQ = M5

MEASUREMENT TECHNIQUE
For input frequencies between 2.5 and 1300 MHz, the Modulation Analyzer tunes its local oscillator (LO) to the signal and down-converts it to an intermediate frequency (IF). The IF signal is amplified, limited, and counted. The LO frequency is also counted. The IF is subtracted from the LO frequency and the result is displayed.

For input frequencies below 2.5 MHz the RF input signal passes directly into the IF without down-conversion. The IF is counted and displayed.
COMMENTS

Input/Output Status

When the instrument is measuring input frequency, the output signal at MODULATION OUTPUT/AUDIO INPUT represents the last modulation measurement made as indicated by the MODULATION OUTPUT annunciator.

Relative Measurements

If RF frequency is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Limiting Low-Level Signal Measurements

When the Error Message Disable Control special function is in the automatic selection mode (Special Function 8.0), very low-level signals can be counted without generating error messages (Error 03 for example). However, other Special Function 8 codes enable error messages at much higher signal levels. (Refer to Error Message Disable Control on page 3-233.)

Centering the IF Does Not Affect Frequency Measurements

It is important to note that when FREQ is selected, the IF need not be exactly centered to make valid frequency measurements. A frequency is displayed as long as a signal is present in the IF. Using the kHz (up arrow) or kHz (down arrow) functions will not change the displayed input frequency even though tuning has been altered. If desired, the frequency error function can be used to indicate tuning error if desired.
Frequency Agile Sources

For best results, use the manual-tune mode when working with frequency agile sources. With agile frequency sources (such as frequency synthesizers), it is possible for the carrier or its harmonics to hop unexpectedly into the IF passband either directly (for frequencies below 2.5 MHz), by normal down-conversion, or by down-conversion of an image (the signal frequency minus the LO approximately equals the IF). Depending on the frequency, amplitude, and timing of the signal source and the tuning mode of the Modulation Analyzer, a tuning error may or may not be sensed. If the instrument does not retune, frequency and level measurement results may not be as expected.

When Measuring Frequency Agile Sources or Multiple Signal Sources

Whenever tuning to signals less than 2.5 MHz, the input signal passes directly into the IF. The LO is used only to turn on the mixer. The Modulation Analyzer sets the LO to 101.5 MHz, a passband is created from 99 to 104 MHz. If this frequency band causes a measurement problem, manually tune the LO so the passband for the down converted signal falls in an unoccupied region of the input spectrum. This method is not a preferred way to make measurements, but it might enable you to make some desired measurements. Note that when using this method you should disable Error 01 (by selecting 8.1 SPCL) to prevent the Modulation Analyzer from trying to tune to a down-converted signal rather than the signal that is less than 2.5 MHz.

Manual Tuning

When tuning manually, it is possible to accidentally adjust the LO so that the input signal falls in the image passband; for example, when using the kHz (up arrow) and kHz (down arrow) keys. Frequency measurements are inaccurate when the instrument is tuned to an image. (Refer to RF Frequency Tuning on page 3–115 for an illustration of the image passbands.)

Input/Output Status

When the FREQ key is selected, the MODULATION OUTPUT signal continues to be the last selected modulation signal, filtered, and/or de-emphasized (except PRE DISPLAY) as previously selected (as indicated by the MODULATION OUTPUT annunciator). Calibration of this output depends on the IF signal level and should be assumed only when all errors are enabled (Special Function 8.8).
RF Frequency Tuning

FUNCTIONS

TRACK MODE, AUTO TUNING, DISPLAY FREQ INCR, kHz † and kHz ‡ keys

DESCRIPTION

The Modulation Analyzer is considered tuned to an input signal when the frequency of the Local Oscillator (LO) produces an IF signal centered in the IF passband. Normally the LO frequency is tuned either 1.5 MHz or 455 kHz above the input signal, depending on which IF is selected. When the input signal is less than 2.5 MHz, the LO is tuned to 101.5 MHz and the input passes directly into the IF.

The Modulation Analyzer can be automatically or manually tuned to the input signal:

In automatic tuning, the instrument searches for the presence of a signal over the entire input spectrum. Once found, the LO is tuned so that the signal is centered properly in the IF.

In manual tuning, the desired input frequency is entered via the numeric keyboard or kHz † and kHz ‡ keys, and the LO is tuned so that a signal of that frequency would be centered properly in the IF.

For both of these tuning modes, the LO can be configured to lock itself to an internal crystal oscillator (for low-noise measurements) or to track the input signal as it drifts (keeping the down-converted signal centered in the IF).

The four tuning modes are listed below:

• Automatic Tuning; Low-noise LO
• Automatic Tuning; Track Mode,
• Manual Tuning; Low-noise LO, and
• Manual Tuning; Track Mode.

Automatic Tuning—Low-Noise LO

If not already tuned, the Modulation Analyzer searches throughout its frequency range for an input signal. If two input signals have similar power levels, the higher frequency signal is usually selected. The RF input signal's second and third harmonic levels must be at least 10 dB below the level of the fundamental, and all other signals at the input must be at least 30 dB below the level of the desired signal. Once tuned, the LO is locked to an internal, voltage-controlled, crystal oscillator for highly-stable, low-noise measurements. Tuning is maintained as long as a detectable signal is present. If the input signal disappears (drops below −20 to −25 dBm), the Modulation Analyzer initiates a signal search. This tuning mode is selected whenever Automatic Operation is pressed and when the instrument powers-up.

Automatic Tuning—Track Mode

The instrument searches for the input signal in the same way as described in the previous paragraph; however, it does not lock to the internal reference oscillator. Instead, the LO is locked to the input signal itself and tracks it as it drifts. This function is useful for checking modulation or level as a function of carrier frequency. If the input signal disappears (for example, when the LO switches bands) the Modulation Analyzer searches for, and re-acquires the input signal. Track Mode tuning is not allowed with the 455 kHz IF or with input signals below 10 MHz. Track Mode tuning somewhat attenuates low-rate FM on the input signal; thus, FM measurements should only be made in track mode when modulation rates exceed 1 kHz. Also, Track Mode tuning is not recommended where optimum noise performance is required.
**Manual Tuning–Low-Noise LO**

The instrument tunes to the frequency keyed into it, via the keyboard, regardless of whether a signal is present. Once tuned, the LO is locked to an internal voltage-controlled, crystal oscillator for high stability and low noise. Once locked, tuning does not change unless a new frequency is entered. Track Mode is selected, the tuning is stepped up or down using the kHz ↑ or kHz ↓ keys. Automatic Operation or Instrument Preset is selected. The manual tune mode is entered immediately when either MHz, kHz ↑, or kHz ↓ is selected; or if Range Hold is selected.

**Manual Tuning–Track Mode**

The Modulation Analyzer tunes to the keyed-in frequency in the same way as described in the previous paragraph. However, the LO is not locked to an internal oscillator; instead the LO is locked to the input signal itself and tracks it as it drifts. This function is useful for measuring second or third harmonic signals and for tracking spurious signals.

**PROCEDURE**

Select FREQ, then:

**Tune Mode Selection**

- Select automatic tuning with AUTOMATIC OPERATION or AUTO TUNING (Blue Key, TRACK MODE).
- Select manual tuning with either MHz or one of the kHz keys (with or without a preceding numeric entry), or with RANGE HOLD.
- Select track mode with TRACK MODE. (Return from the track mode to the low-noise mode, by selecting TRACK MODE again.)

**Manual Tuning by Keyboard Entry**

To manually tune to a specific signal frequency, enter the frequency in MHz via the numeric keyboard, then press the MHz key.

The MHz key can also be used alone to aid in tuning: if the Modulation Analyzer is tuned close but not exactly to the input signal, select MHz to center the signal in the IF passband. If in automatic tuning mode, and no signal is present, select MHz alone to tune the Modulation Analyzer to the last frequency at which a signal was successfully tuned. (If no previous successful tuning has been made, the Modulation Analyzer tunes to 100 MHz.)

**RF Frequency Stepping**

To step the tuning of the Modulation Analyzer, enter the desired frequency step size in kHz via the numeric keyboard, then press either kHz ↑ or kHz ↓. Once the step size has been set, either kHz key will change the tuning by that step size each time the key is pressed. (At power-up, the step size is set to 0 kHz.)
HP-IB PROGRAM CODES

When operating the Modulation Analyzer via HP-IB, the units for the frequency steps can be either Hz or kHz.

**AUTO TUNING = AT**
**AUTOMATIC OPERATION = AU**
**Display Frequency = FR**
**Display Increment = FN**
**Hz, Input Frequency Entry = HZ**
**MHz, Input Frequency Entry = MZ**
**Ranging Automatic = G0**
**RANGE HOLD = G1**
**Step Up (Hz) = HU**
**Step Down (Hz) = HD**
**Step Up (kHz) = KU**
**Step Down (kHz) = KD**
**TRACK MODE off = K0**
**TRACK MODE on = K1**

COMMENTS

**RF Frequency Stepping**

Using the kHz ↑ and kHz ↓ keys, the tuning of the Modulation Analyzer can be changed by a selectable frequency step (in kHz). This feature is most often used in conjunction with the frequency error function. The kHz keys can be used regardless of tune mode, but when pressed, the tuning mode reverts to manual tuning. If these keys are pressed in an automatic tuning mode, the instrument will tune tuning to the last successfully tuned frequency plus or minus the frequency step. Once a frequency step is entered on the keyboard (refer to “PROCEDURE”), pressing either of the kHz keys alone will change tuning by that step size until a new step frequency is defined. At power-up, the step size is zero.

**HP-IB**

RF frequencies can be changed in fundamental-units (Hz) steps via the HP-IB. These steps are not possible from the front panel:

**Hz Step Up = HU**
**Hz Step Down = HD**

**Tuning to Signals with Low-Rate, High-Deviation FM**

The instrument will not automatically tune to a signal that has low-rate, high-deviation FM. Use a manual tune mode to measure such signals.

**Tuning to Signals with Narrow-Band FM and φM**

The automatic tuning, low-noise LO mode is adequate for most common measurements. It should always be used for measuring narrow-band FM and φM.

**Measuring Flatness as a Function of Carrier Frequency**

Automatic tuning, track mode is useful for measuring modulation or peak tuned RF level flatness as a function of carrier frequency. (Select TUNED RF LEVEL.)
Tuning to Low-Level Signals

Manual tuning, low-noise mode should be used with signals that may drop below the minimum threshold for automatic tuning. Manual tuning makes it possible to make tuned modulation and frequency measurements on very low-level signals.

Measuring Drift

Manual tuning, track mode is useful for measuring drift on low-level signals in the presence of higher-level signals.

Determine Tuning Accuracy

When manually tuning or frequency stepping, use the frequency error measurement to determine tuning accuracy.

Image Frequencies

When the Modulation Analyzer tunes to an input signal greater than 2.5 MHz, the IF frequency positions the internal LO above the nominal tuning. The Modulation Analyzer, however, will respond equally well to a signal at the image frequency, that is, when the signal frequency minus the LO is within the IF passband. (For example, if the LO is at 101.5 MHz, signals at either 100 MHz or 103 MHz (the image) generate a 1.5 MHz IF.) When the instrument is tuned to an image, measurement errors may result with no Error Message displayed. (The input frequency measurement will always be in error. For FM and PM measurements, the Peak+ and Peak− functions are reversed. One way to solve this problem is to step the tuning down by twice the IF frequency, or let the instrument automatically tune. The following IF response plot illustrates the image passbands for each IF frequency. (Tuned RF Level does not apply.)

455 kHz and 1.5 MHz IF Passband Responses

When Measuring Frequency Agile Sources or Multiple Signal Sources

Whenever tuning to signals less than 2.5 MHz, the input signal passes directly into the IF. The LO is used only to turn on the mixer. However, since the Modulation Analyzer arbitrarily sets the LO to 101.5 MHz, a passband is created from 99 to 104 MHz. If this frequency band causes a measurement problem, manually tune the LO so the passband for the down converted signal falls in an unoccupied region of
the input spectrum. This method is not a preferred way to make measurements, but it might enable you to make some desired measurements. Note that when using this method you should disable Error 01 (by selecting 8.1 SPCL) to prevent the Modulation Analyzer from trying to tune to a down-converted signal rather than the signal that is less than 2.5 MHz.

Frequencies Greater Than 10 MHz

When making measurements on inputs with frequencies greater than 10 MHz, signals present at the input that are less than 2.5 MHz pass directly into the IF. These low-frequency signals can be removed by inserting the RF input high-pass filter. (Refer to Filters, RF and IF on page 3–229).

Searching for a Signal

When manually tuning, often the exact input frequency is unknown. If during tuning, Error 01 (signal out of IF range) is displayed, select the MHz key alone to center the signal in the IF. Also, if searching for a signal using the kHz keys, it is best to search down from above the signal frequency while monitoring IF LEVEL. (Refer to IF Level on page 3–93.) When the IF level rises significantly, switch to FREQ ERROR and enter the displayed value as a frequency step and complete tuning using the kHz keys.

Default Conditions

When the Instrument Preset key is pressed, or on power-up, the Modulation Analyzer selects the automatic tuning, low-noise LO mode.

Responding to Frequency Changes

Using the automatic tune mode, the Modulation Analyzer might not retune when the frequency changes, but its spectrum still has sufficient power within the tuned passband of the Modulation Analyzer’s RF INPUT. It will appear that the carrier simply changed its level. If the instrument does not retune, frequency and level measurement results might not be as expected. Use a manual tune mode, if possible, in the following situations:

- When working with frequency agile sources (such as frequency synthesizers) that have a frequency hopping function.
- When changing frequency in harmonic steps.

Extending Tuned Measurements Below 2.5 MHz

Use the following procedure to extend the range of tuned measurements below 2.5 MHz.

**NOTE**

*Only the 455 kHz IF can be selected. The minimum input frequency is 795 kHz. Measurement accuracy may be degraded. IF signal may appear at the modulation monitoring connectors.*

1. Select INSTR PRESET (Blue Key, AUTOMATIC OPERATION).
2. Set the signal source to a carrier frequency between 3 and 9 MHz and to the level of the intended measurement.
3. Connect the signal source to the Modulation Analyzer's INPUT (or to a properly connected sensor module). Allow the Modulation Analyzer to tune to the input signal.
4. Select RANGE HOLD. Select DISABLE ERROR (Blue Key, RANGE HOLD).
5. Enter the frequency value of the input signal and retune the signal source to that frequency.
6. Select the desired measurement mode. (RANGE HOLD and DISABLE ERROR can be released at this time.)
RF Frequency Error

FUNCTIONS
FREQ ERROR

DESCRIPTION
The Frequency Error function enables the Modulation Analyzer to measure the difference (in kHz) between the RF input signal frequency and the frequency to which the instrument is tuned. This function can be used to observe frequency drift of input signals, or to compare input frequencies against a keyboard-entered reference.

Display resolution is controlled by Special Function 7. (Refer to RF Frequency Resolution on page 3–131.)

PROCEDURE
To make the RF frequency error measurement, connect the RF signal to the Modulation Analyzer’s RF INPUT.

If a frequency drift measurement is to be made, first allow the Modulation Analyzer to automatically tune to the signal, then select the MHz key to prevent retuning. Select FREQ ERROR (Shift, FREQ) to display the frequency error. As the signal drifts, the display indicates the magnitude and direction of the drift.

To make a frequency comparison, enter the reference frequency (in MHz) on the keyboard, then select MHz. Select FREQ ERROR to display the difference frequency. The number is negative if the signal frequency is lower than the reference, and positive if the signal frequency is higher than the reference. Valid frequency error measurements are made as long as the down-converted signal remains in the IF passband. (Refer to RF Frequency Tuning on page 3–115.)

EXAMPLE
To measure the error of an oscillator designed to operate at 30 MHz, connect the oscillator’s output to the Modulation Analyzer’s RF INPUT connector and select the following keystrokes:

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>LOCAL (program codes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 0</td>
<td>30 MZ S5</td>
</tr>
<tr>
<td></td>
<td>RF-1B</td>
</tr>
</tbody>
</table>
**HP-IB PROGRAM CODES**

FREQ ERROR = S5  
MHz = MZ

**MEASUREMENT TECHNIQUE**

When the Modulation Analyzer is tuned, the IF signal is amplified and limited. If manually tuned, the RF input frequency is measured and compared to either the keyboard-entered frequency or to the frequency measured after the MHz key is pressed. The frequency difference is displayed as frequency error.

If the Modulation Analyzer is automatically tuned, two methods of determining frequency error are used:

- When the input signal is greater than 2.5 MHz, the frequency of the actual IF signal is subtracted from the selected IF frequency (455 kHz or 1.5 MHz) to determine the frequency error.

- When the input signal is less than 2.5 MHz, the input signal is passed directly into the IF without down-conversion. When the signal is first located, the frequency is counted. When the FREQ ERROR key is selected, this first-counted frequency becomes the reference. Subsequent frequency counts are subtracted from this reference, and the results are displayed as frequency error.

![RF Frequency Error Measurement Block Diagram](image)

**COMMENTS**

**Down-Converted Signals**

The down-converted RF input frequency must fall within the passband of the IF being used. For the 1.5 MHz IF, the passband is approximately 3 MHz wide. For the 455 kHz IF, the passband is approximately 200 kHz wide.
Input/Output Status

When the instrument is measuring frequency error, the output signal available at MODULATION OUTPUT/AUDIO INPUT is the same as for the last modulation measurement (as indicated by the MODULATION OUTPUT annunciator).

Relative Measurements

If frequency error is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Use Manual Tuning for Best Measurements

The frequency error function can be used with the automatic tuning low-noise LO tune mode, but it is most valuable when used with manual tuning (normal or Track Mode). It is not recommended that frequency error be used when in automatic tuning track mode, since an inherent tuning offset exists in this mode.

Step Frequency Aids Multi-Channel Measurements

Check channel accuracy on multi-channel transmitters using the frequency error function in conjunction with the kHz † and kHz ‡ keys. Set the step frequency to the channel spacing to quickly determine the accuracy of evenly-spaced channels.

LO in Image Passband Distorts Measurements

When tuning manually, it is possible to accidentally adjust the LO so that the input falls in the image passband; for example, when using the kHz † and kHz ‡ keys. Frequency error measurements are inaccurate when the input image enters the IF passband. Refer to RF Frequency Tuning on page 3-115 for an illustration of the image passbands.

Changing Resolution

Normally, the counter updates the display five times each second. For selection of other resolutions, use Special Function 7. (Refer to RF Frequency Resolution on page 3-131.) Counter accuracy is the reference accuracy ±3 counts.

Input/Output Status

When the Frequency Error function is selected, MODULATION OUTPUT/AUDIO INPUT continues to output the last-selected modulation signal, filtered and/or de-emphasized (except PRE DISPLAY) as previously selected. The calibration of this output depends on the input signal level and should be assumed only when all errors are enabled (Special Function 8.8).

Parts Per Million Display

To display frequency error in parts per million (ppm), first display the frequency error, then enter 1/10 the reference frequency (in MHz) as a ratio reference, and select RATIO. The display shows the frequency error in parts per million.
IF Frequency

FUNCTIONS

Special Function 34 (IF Frequency)

DESCRIPTION

The Modulation Analyzer makes tuned (down-converted, heterodyned) measurements on its RF input signal using one of two IF frequencies. Three combinations of tuning and IF selection are used:

1. When RF input signals less than 2.5 MHz are measured, the RF input signal passes directly into the IF without down-conversion; that is, the RF input frequency and the IF frequency are the same. (Tuned measurements can be manually extended below 2.5 MHz. Refer to RF Frequency Tuning on page 3–115.)

2. When RF input signals greater than 2.5 MHz, but less than 10 MHz are measured, the signal is down-converted to a 455 kHz IF.

3. When RF input signals greater than 10 MHz are measured, the signal is down-converted to a 1.5 MHz IF. (Note that special Function 3 can be used to select the 455 kHz IF. Refer to Filters, RF and IF on page 3–229.)

Special Function 34.0 enables the Modulation Analyzer to measure and display the IF frequency for the signal being measured.

PROCEDURE

To measure the IF frequency, key in 34.0 SPCL.

MEASUREMENT TECHNIQUE

The IF signal, generated when the Local Oscillator and the RF input signal mix, is amplified by the IF Amplifier and FM Limiters and then counted. The IF frequency is displayed when Special Function 34 is used. When measuring RF input frequencies greater than 2.5 MHz, the Modulation Analyzer uses either the 455 kHz or 1.5 MHz IF. For RF input frequencies less than 2.5 MHz, down-conversion is not normally used and the RF input signal passes directly into the IF.

BLOCK DIAGRAM

[Diagram of IF Frequency Measurement Block Diagram]

IF Frequency Measurement Block Diagram
COMMENTS

Input/Output Status

When the instrument is measuring IF frequency, the signal at MODULATION OUTPUT/AUDIO INPUT remains unchanged.

Relative Measurements

If IF frequency is to be displayed relative to a reference, enter the ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Frequency Resolution

Normally, the counter updates the display five times each second. For selection of other resolutions, use Special Function 7. (Refer to RF Frequency Resolution on page 3-131.) Counter accuracy is the reference accuracy $\pm 3$ counts.

IF Filter Selection

IF filter selection is dependent on the selected IF Frequency. (Refer to Filters, RF and IF on page 3-229.)

When using the 455 kHz IF on input signals with frequencies greater than 300 MHz, incidental AM (that is, AM due to FM) increases substantially.

RF Input Frequency Calculation

The Modulation Analyzer determines the frequency of the RF input signal by counting the frequencies of both the IF and LO and calculating their difference.

IF Frequency Accuracy

The IF frequency need not be exactly its nominal value in order to guarantee accurate modulation measurements. Unless specifically overridden by Special Function 8 or DISABLE ERROR (Blue Key, RANGE HOLD), Error Messages safeguard the measurements. (Refer to Error Message Disable Control on page 3-233 and RF Frequency Tuning on page 3-115.)
LO Frequency

FUNCTIONS
Special Function 33 (LO Frequency)

DESCRIPTION
Special Function 33.0 enables the Modulation Analyzer to display the local oscillator (LO) frequency.

PROCEDURE
To measure the LO frequency, key in 33.0 SPCL.

MEASUREMENT TECHNIQUE
The LO frequency is essentially measured directly by the counter. The frequency that the LO is tuned to depends on (1) whether automatic tuning or manual tuning is being used, (2) whether the RF input signal is being down-converted, and (3) which IF is being used. The following table summarizes LO tuning. (Refer to RF Frequency Tuning on page 3-115 for more information.)

BLOCK DIAGRAM

![LO Frequency Measurement Block Diagram](image)

LO Frequency Measurement Block Diagram

LO Frequency 3-127
COMMENTS

Input/Output Status.
When the instrument is measuring the LO frequency, the signal at MODULATION OUTPUT/AUDIO INPUT remains unchanged.

Relative Measurements.
If the LO frequency is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

Display Resolution.
Normally, the counter updates the display five times each second. For selection of other resolutions, use Special Function 7. (Refer to RF Frequency Resolution on page 3-131.) Counter accuracy is the reference accuracy ±3 counts.

LO Does Not Phase Lock to INPUT.
In general, LO tuning is never exact but is close enough to give calibrated measurements. The LO does not phase lock to the RF input signal.

LO Frequency for INPUT Less Than 2.5 MHz.
When the RF input signal is less than 2.5 MHz, the LO frequency is set to 101.5 MHz. This frequency is arbitrary. The LO must remain on to allow the RF input signal to pass through the input mixer. Note that 101.5 MHz is the frequency the LO is set to for a 100 MHz RF input signal with an IF of 1.5 MHz.
LO Input and LO Output (Option 003)

**CAUTION**

Do not apply greater than 40 Vdc or +5 dBm of RF power into the LO INPUT or damage to the instrument may result. Do not apply dc voltage or RF power into the LO OUTPUT or damage to the instrument may result.

**DESCRIPTION**

In Modulation Analyzers with Option 003, the internal local oscillator (LO) signal is routed through the rear-panel LO OUTPUT and LO INPUT connectors. The range of the LO signal is 1.27 MHz to 1301.5 MHz, at approximately 0 dBm. Both connectors are 50Ω, ac-coupled, Type-N connectors.

**NOTE**

The rear-panel LO OUTPUT must be connected to the rear-panel LO INPUT for normal Modulation Analyzer operation that uses the internal local oscillator.

**BLOCK DIAGRAM**

LO Input and LO Output Block Diagram
PROCEDURE

To use LO OUTPUT as a signal source:

1. Select an IF frequency of either 1.5 MHz or 455 kHz using Special Function 3. (If the IF frequency is not specified, the Modulation Analyzer will assume the 1.5 MHz IF for keyboard-entered frequencies greater than 10 MHz and the 455 kHz IF for frequencies less than 10 MHz but greater than 2.5 MHz.)

2. Subtract the IF frequency from the frequency desired at LO OUTPUT, and enter the result, in MHz, via the numeric keys; then press the MHz key. (To tune the LO below 2.96 MHz, use the procedure as described, but select the 455 kHz IF using Special Function code 3.1, and disable Error 01 using Special Function code 8.1.)

3. Connect the LO OUTPUT to the desired input.

The LO frequency can be monitored using Special Function 33. (Refer to LO Frequency on page 3–127.)

To use an external source as the LO INPUT:

1. Select an IF frequency (1.5 MHz or 455 kHz) using Special Function 3.

2. Press the MHz key to enter manual tune mode (to prevent the internal LO from continuously tuning).

3. Add the IF frequency to the frequency to which the Modulation Analyzer is to be tuned, and set the external LO to that frequency.

4. Adjust the external LO to 0 dBm and connect it to the LO INPUT.

COMMENTS

Using the LO OUTPUT

LO tuning is not exact. The instrument tunes the LO only close enough to make calibrated measurements.

Using the LO INPUT

To tune to inputs below 2.5 MHz with an external LO, select the 1.5 MHz IF, but set the LO to approximately 100 MHz. LO signal is required for the Input Mixer to function even when down-conversion is not desired.

Invalid Frequency Measurements (RF and LO)

When an external LO is used, measurements made using the FREQ or FREQ ERROR keys are invalid. To determine input frequency, subtract the IF frequency (34.0 SPCL) from the LO frequency used.

The LO frequency function (33.0 SPCL) continues to measure the internal LO.

FM Transients Using an External LO

When using an external LO, rapid changes in LO frequency within the IF passband cause FM transients. Several seconds are then required before accurate measurements are possible. To avoid the problem, turn off the external LO when switching its frequency.
RF Frequency Resolution

FUNCTIONS

Special Function 7 (RF Frequency Resolution)

DESCRIPTION

When making RF measurements, the frequency resolution can be manually set using Special Function 7. When RF frequency measurements are made, the Modulation Analyzer normally updates the display five times each second. The instrument automatically selects 10 Hz resolution for frequencies below approximately 2.5 MHz; 100 Hz resolution for frequencies from approximately 2.5 to approximately 320 MHz; and 1000 Hz resolution for frequencies greater than approximately 320 MHz. Use the numeric keyboard and the SPCL key to set the frequency resolution to either 1000, 100, or 10 Hz. (A resolution of 0.1 Hz or 1 Hz can be selected for RF frequency measurements.)

Special Function 7 sets the measurement resolution for RF Input Frequency, RF Frequency Error, IF Frequency, and LO Frequency Measurements.

PROCEDURE

To set the frequency resolution to a selected range or to re-enter the automatic selection mode, key in the corresponding Special Function code, then SPCL: (Note that with finer resolution, measurement time increases.)

7.0 Automatic selection.
7.1 Resolution of 10 Hz.
7.2 Resolution of 100 Hz.
7.3 Resolution of 1 kHz.
7.4 (Applies to RF Frequency measurements only; other measurements treat 7.4 as 7.1.) Resolution of 0.1 Hz for input signals less than 10.1 MHz; resolution of 1 Hz for signals from 10.1 MHz through 1300 MHz. (When measuring frequencies as high as 1300 MHz, measurement time with this resolution is approximately 20 seconds.)

COMMENTS

Change Resolution Any Time

The Modulation Analyzer need not be making RF frequency measurements in order to change resolution modes; however, the resolution mode only affects RF frequency-related measurements. Counter accuracy is the reference accuracy +3 counts.

RF Frequency Measurements Greater Than 20 GHz

When making RF frequency measurements greater than 20 GHz, 7.1 SPCL selects 100 Hz resolution.

---

1 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.

AM

FUNCTIONS

AM, Special Function 2 (Audio Range)

DESCRIPTION

Selecting AM enables the Modulation Analyzer to measure the AM depth of the tuned RF input signal. (Selecting Special Function 2 sets measurement limits on the range of AM depth at the same time a specific display resolution is set.)

AM measurements are specified for rates from 20 Hz to 10 kHz for carrier frequencies 10 MHz and below (or whenever the 455 kHz IF is used) and from 20 Hz to 100 kHz for carrier frequencies from 10 to 1300 MHz (1.5 MHz IF only). The corresponding 3 dB audio bandwidths are approximately 0.5 Hz to 15 kHz for carriers 10 MHz and below (or with the 455 kHz IF) and approximately 0.5 Hz to 260 kHz for carriers from 10 to 1300 MHz (1.5 MHz IF only). (Special Function 6.1 will modify the lower frequency.) Modulation depths to 99% can be measured.

The demodulated signal's frequency and distortion can also be measured. (Refer to Audio Measurements section which starts on page 3-197.)

PROCEDURE

To make an AM measurement, first tune the instrument to the input signal by selecting AUTOMATIC OPERATION. Select AM.

Select an audio detector: PEAK+, PEAK−, PEAK±/2, AVG, or RMS. The RMS detector (Blue Key, AVG) is less accurate than the other detectors in measuring AM, has a reduced bandwidth, and is typically only used for audio distortion measurements.

The following table lists the different measurement range limits that can be selected with Special Function 2:

<table>
<thead>
<tr>
<th>Modulation Range Peak± (%)</th>

</tr>
</tbody>
</table>

HP-IB PROGRAM CODES

All HP-IB codes for setting a limit or a specific display resolution for modulation-depth measurements are provided in “Procedures”.

AM = M1
SPCL = SP

MEASUREMENT TECHNIQUE

The AM Demodulator measures AM as a ratio of the demodulated audio signal level to the average tuned carrier level. An automatic level control (ALC) loop within the AM Demodulator holds the carrier level constant so that the percent AM is proportional to the peak amplitude of the demodulated audio output. This audio output is then filtered, audio detected, and displayed as % AM. The demodulated AM is available at MODULATION OUTPUT/AUDIO INPUT (unless AUDIO INPUT is selected).

AM Measurement Block Diagram
COMMENTS

Input/Output Status

The demodulated AM is present at MODULATION OUTPUT/AUDIO INPUT (unless AUDIO INPUT has been selected). The demodulated AM is usually present at the rear-panel AM OUTPUT connector. (Refer to AM Output on page 3-147.)

Peak±/2 Detector

The PEAK+ detector always detects the peak of the carrier envelope while the PEAK_ detector always detects the trough. The PEAK±/2 detector sums the peak and the trough readings and divides the total by two to provide an average of the two peak values. (Do not confuse this “average” value with the detected average value.)

Automatic Range Selection

The routine which automatically selects the modulation range contains a region of overlap between 35 and 40% AM (peak detected). When using the average or RMS detectors, ranging occurs at readings lower than these. In general, if the modulation is reduced from above 40% into the overlap region, only 0.1% resolution is ordinarily displayed although 0.01% resolution is available. To display the increased resolution, press the AM key a second time. Audio Range has more detailed information on the modulation ranges that can be set.

Automatic Filter Selection

When operating above 2.5 MHz, while using the 455 kHz IF, the upper limit of the demodulated signals modulation rate is that of the 20 kHz LP Filter. The 15 kHz LP Filter is automatically selected when operating below 10 MHz or whenever the 455 kHz IF is selected. However, this filter may be overridden by selecting another LP Filter. The lower limit of the modulation rate is determined by the ALC response time selected. (Refer to AM ALC Response Time on page 3-139.)

Inverted Output Signal

The signal at the rear-panel AM Output is inverted relative to the Modulation Output signal.

Potential Inaccuracies

AM conditions that cause the carrier signal to disappear (such as 100% AM or pulse modulation) will cause inaccuracies in measurement of FM, FM, or input frequency, or they could cause Error 05 (FM squelched) to be displayed when these measurements are selected.

Increased Accuracy

Accuracy of AM readings may be improved by calibrating the AM measurement (refer to AM Calibration on page 3-141) and by taking into account the effects of residual noise (refer to Residual Noise Effects on page 3-191).

Relative AM Depth Measurements

If AM depth is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)
AM ALC Response Time

FUNCTIONS
Special Function 6 (Automatic Level Control)

DESCRIPTION
The Modulation Analyzer normally uses a slow-responding AM automatic level control (ALC) circuit, allowing AM rates as low as 20 Hz to pass unaffected by the leveling loop. (Refer to the figure in AM, "Measurement Technique.")

Select a fast ALC response time to speed up the measurement settling time required for varying carrier levels. The faster ALC response time degrades AM accuracy at rates less than 1 kHz.

The ALC can be disabled. This feature, used in conjunction with the rear-panel AM Output connector, is useful for measuring AM at very low modulation rates. Disabling the ALC also permits measuring absolute changes in depth without regard to changes in carrier level (a feature that is useful in characterizing amplitude modulators).

PROCEDURE
The instrument normally operates with a slow AM ALC response time. To change the response time, or to disable the ALC, enter the corresponding Special Function code, then select SPCL.

<table>
<thead>
<tr>
<th>AM ALC Response</th>
<th>Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slow ALC (AM rates &gt;20 Hz)</td>
<td>6.0 SPCL</td>
<td>6.0SP</td>
</tr>
<tr>
<td>Fast ALC (AM rates &gt;1 kHz)</td>
<td>6.1 SPCL</td>
<td>6.1SP</td>
</tr>
<tr>
<td>ALC off</td>
<td>6.2 SPCL</td>
<td>6.2SP</td>
</tr>
</tbody>
</table>

HP-IB PROGRAM CODES
For HP-IB codes, refer to “PROCEDURE”.

COMMENTS

Default Condition
When the instrument is first turned on, or when Automatic Operation or Instrument Preset is selected, the slow ALC response is selected.

IF Level Dependency
The displayed modulation depth and the sensitivity of the Modulation Output connector for AM demodulation are incorrect when the ALC is disabled unless the IF level is 100%. (Refer to IF Level on page 3-93.)
AM Calibration

FUNCTIONS

CALIBRATE, SAVE CAL, % CAL FACTOR, Special Functions 13 (AM Calibration) and 16 (AM Calibration Factors).

DESCRIPTION

The accuracy of the Modulation Analyzer’s AM demodulator can be checked with the internal AM calibrator. The calibration process generates a calibration factor to compensate for the AM measurement error (within the accuracy limits of the AM Calibrator). Using the SAVE CAL key or Special Function 16, the calibration factor can then be enabled to automatically correct the measured AM error in subsequent measurements. With the calibration factor enabled, AM measurements can be made with an accuracy typically better than 0.5%. The calibration factor can be enabled, disabled, or displayed at any time.

Other instruments in the HP 8901 and 8902 RF signal analyzer family can be calibrated or cross checked using Special Function 13.

PROCEDURE

Self-calibration

To determine the measurement error of the Modulation Analyzer’s AM demodulation circuits, first allow at least a half-hour continuous operation before calibration, then perform the following steps:

1. Connect the CALIBRATION AM/FM OUTPUT to the RF INPUT with a 50Ω cable (or a sensor module with an internal switch such as the HP 11722A) and select AM.

2. Select CALIBRATE. After several seconds, the AM calibration factor is displayed in % and stored (but not enabled unless already enabled).

The instrument displays 100.00% if no error is measured. A display of 100.17% means the AM demodulator in the Modulation Analyzer is reading 0.17% high. As long as the CALIBRATE key light is on and the cable is connected, calibration repeats and the AM calibration factor is updated approximately every 17 seconds. To turn off the calibrator, select CALIBRATE or any Measurement key.

NOTE

*For optimum accuracy, the instrument should be continuously operating for at least one half hour before calibration is performed. In addition, the first two AM Calibration Factors received after instrument power-up should not be used even if the instrument is already warm, since the circuits in the audio chain may not be fully settled.*

Correcting Measurements with the AM Calibration Factor. Once a calibration factor has been determined, the instrument retains that value in its non-volatile memory. This factor may be enabled to automatically correct AM measurements. The calibration factor can also be disabled or displayed.

Selecting % CAL FACTOR or 16.2 SPCL displays the calibration factor being used.
Enter the appropriate front-panel key or Special Function code to manipulate the AM Calibration Factor as described in the following table:

<table>
<thead>
<tr>
<th>Action: AM Calibration Factor</th>
<th>Measurement Mode</th>
<th>Front-Panel Key or Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable</td>
<td>Any</td>
<td>16.0 SPCL</td>
<td>16.0SP</td>
</tr>
<tr>
<td>Enable (From CALIBRATE mode)</td>
<td>(Blue Key)</td>
<td>SC</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SAVE CAL</td>
<td>16.1SP</td>
<td>16.1SP</td>
</tr>
<tr>
<td>Display</td>
<td>Any</td>
<td>% CAL FACTOR*</td>
<td>CF</td>
</tr>
<tr>
<td></td>
<td>(Blue Key)</td>
<td>16.2 SPCL</td>
<td>16.2SP</td>
</tr>
</tbody>
</table>

* The % CAL FACTOR key displays the status of the calibration factor. The factor is enabled if the value of the calibration factor is displayed, with 0.01% resolution. The factor is disabled if 100% is displayed. (Note the resolution of 1%. A display of 100.00% would be a true, uncalibrated factor reading.)

**Calibrating or Cross Checking Another HP 8901 or 8902 RF Signal Analyzer**

To compute an AM calibration factor for another RF signal analyzer that has no internal calibrator, or that has an internal calibrator that is to be cross checked, use the Modulation Analyzer and its calibrator as follows:

1. Connect the Modulation Analyzer's CALIBRATION AM/FM OUTPUT to the RF input of the other RF signal analyzer.
2. Select 13.0 SPCL for the Modulation Analyzer. Record the value that appears on the display. This is the computed, calibrated, peak AM depth (excluding noise).
3. Select 13.1 SPCL for both instruments. Record the value that appears on the display of the RF signal analyzer. (If display jitter makes readings difficult, select 5.1 SPCL.) The displayed value is the weighted, peak, residual AM depth of the calibrator's unmodulated output as demodulated by the RF signal analyzer.
4. Select 13.2 SPCL for both instruments. Record the value that appears on the display of the RF signal analyzer. This value is the demodulated, positive, peak AM depth of the calibrator's modulated output. (If display jitter makes readings difficult, select 5.1 SPCL.)
5. On the RF signal analyzer, select PEAK-. Note the value displayed on the RF signal analyzer. If the difference between the results of steps 4 and 5 is three counts or less in the least significant digit, an average between the two need not be computed; use the result from step 4. If the difference between the two results is greater than three counts in the least significant digit, compute the average as follows:

\[
(13.2 \text{ result}) = \frac{(\text{result of step 4}) + 2(\text{result of step 5})}{3}
\]

6. Compute the AM calibration factor of the RF signal analyzer as follows:

\[
AM \text{ Calibration Factor (\%)} = 100 \times \frac{(13.2 \text{ result}) - (13.1 \text{ result})}{(13.0 \text{ result})}
\]
7. To use this AM calibration factor to correct AM measurements made with the RF signal analyzer, enter the value as a ratio reference and use the Ratio function in the RF signal analyzer.

The Special Function codes are summarized in the table below:

<table>
<thead>
<tr>
<th>Function</th>
<th>Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display computed peak AM</td>
<td>13.0 SPCL</td>
<td>13.0 SP</td>
</tr>
<tr>
<td>Display demodulated peak residual AM</td>
<td>13.1 SPCL</td>
<td>13.1 SP</td>
</tr>
<tr>
<td>Display demodulated peak AM</td>
<td>13.2 SPCL</td>
<td>13.2 SP</td>
</tr>
</tbody>
</table>

**HP-IB PROGRAM CODES**

HP-IB codes for enabling, disabling, or displaying the internal AM calibration factor are provided in “Procedures”. The HP-IB codes for the AM Calibrator Special Function used to calibrate another RF signal analyzer are also provided as part of “Procedures”:

\[
\begin{align*}
AM &= M1 \\
CALIBRATE \text{ off} &= C0 \\
CALIBRATE \text{ on} &= C1 \\
SPCL &= SP
\end{align*}
\]

**INDICATIONS**

**Self-Calibration**

When the CALIBRATE key is pressed, approximately 17 seconds pass during which the instrument configures itself and tunes to the calibrator’s signal. The display indicates four dashes (--- - -) and lights the % annunciator. Once the AM Calibration Factor has been computed, it is displayed. Subsequent updates occur approximately every 17 seconds.

**Correcting Measurements with the AM Calibration Factor (Self-Calibrated)**

When the calibration factor is enabled, the AM depth measurement is always a corrected measurement. If % CAL FACTOR (Blue Key, MHz) is selected, and the AM calibration factor is enabled, the AM calibration factor is displayed. If % CAL FACTOR (Blue Key, MHz) is selected, and the AM calibration factor is disabled, 100% is displayed. (Note the resolution of 1%.)

**Calibrating Another RF Signal Analyzer**

The Modulation Analyzer displays the computed AM depth (Special Function 13.0), but shows two dashes (-- -) throughout the rest of the procedure.

**MEASUREMENT TECHNIQUE**

When AM and then CALIBRATE are selected, the FM Calibrator sends an unmodulated 10.1 MHz carrier to the AM Calibrator.

The AM Calibrator contains two identical modulators in parallel whose outputs are summed. When the calibration operation is initiated, each modulator is turned on and each individual output level is measured, via an on-board detector, to compute AM depth.

While one of the modulators is on, the residual AM of the calibrator (very low) and the AM demodulator (more significant) are characterized and weighted (refer to *Residual Noise Effects* on page 3-191).
Next, one modulator is left on and the other is toggled on and off at a 10 kHz rate. Since the RF signal is switched between full on and half on, the resultant carrier modulation is very near 33.33%. (The exact depth is derived from the measurements that characterize the individual modulators.) This modulation is then measured by the AM demodulator. (Both peak detectors are used, and their average is computed.)

The Modulation Analyzer compares the modulation depth (static measurements) with the demodulated AM (toggled measurements) and computes its accuracy error as follows:

$$AM\ Calibration\ Factor\ (\%) = \frac{Demodulated\ AM - Demodulated\ Residual\ AM}{Computed\ AM} \times 100$$

All segments of the calibration are carefully monitored. If any segment is out of limits, the calibration is aborted and Error 08 is displayed.

**Simplified Block Diagram of the AM Calibrator**

**COMMENTS**

**Default Calibration Factor**

If the instrument’s non-volatile memory is erased, 100.00% is used as the default calibration factor.

**Updating the AM Calibration Factor**

Whenever AM calibration is performed, the instrument updates the stored AM calibration factor.
Special Function Cancellation
Performing Calibration cancels most special functions.

When Using the AM Calibrator to Calibrate Other Signal Analyzers
The modulation waveform of the AM Calibrator is a rounded squarewave. An RF signal analyzer, which uses it as a calibration standard, must have demodulation and audio-processing circuits which preserve the full fidelity of the waveform.

Automatic AM Ranging
When used to calibrate an RF signal analyzer, Special Functions 13.1 and 13.2 set the AM modulation range to that of 0 to 100% (Special Function 2.1). Upon exiting the AM Calibrator Special Function, the audio ranging is not returned to automatic but remains fixed (thus leaving the SPCL light on). Key in 2.0 SPCL to return the audio ranging to automatic.
AM Output

CAUTION
Do not apply greater than 10 \( V_{pk} \) (ac+dc) into the rear-panel AM OUTPUT connector or damage to the instrument may result.

DESCRIPTION

The rear-panel AM OUTPUT (dc coupled, 10 k\( \Omega \)) output impedance) provides an auxiliary output for the AM demodulated from the RF input signal. This output enables monitoring of AM during display of other measurements (such as FM, \( \Phi \)M, or audio signals).

The output can also be used in conjunction with Special Function 6.2 (described in AM ALC Response Time on page 3–139) to measure AM depth at low modulation rates.

The output signal comprises both a dc voltage (related to the detected IF level) and an ac voltage (bandwidth 16 kHz, one pole proportional to the AM depth). The dc component contains an offset voltage (Voff) which must be subtracted out. The relationship between \% AM and the signal levels at AM OUTPUT is:

\[
\% AM = \frac{V_{pk}}{|V_{dc} - V_{off}|} \times 100\%
\]

where: \( V_{pk} \) is the peak of the ac component,
\( V_{dc} \) is the total dc component, and
\( V_{off} \) is the dc offset voltage.

When the AM ALC is on, the dc level at AM OUTPUT is held constant, thus,

\[
\% AM = K \times V_{pk},
\]

where:

\[
K = \frac{100\%}{V_{dc} - V_{off}}
\]

When the AM ALC is turned off (Special Function 6.2), the dc voltage at AM OUTPUT varies with the signal level (although the offset remains constant), and the full formula must be used for each measurement.

PROCEDURE

To measure AM depth via AM OUTPUT, first determine the offset voltage:

Select AUTOMATIC OPERATION to clear any Special Functions in effect, then connect a dc voltmeter to the AM OUTPUT connector and remove any signal at RF INPUT. Press MHz to fix the tuning, and read the offset voltage on the voltmeter.

Disable the AM ALC loop (6.2 SPCL) and apply the carrier to the RF INPUT. Measure the dc and peak ac signals at AM OUTPUT. Use the first equation in "DESCRIPTION" to compute \% AM.
EXAMPLE

To measure AM depth at AM OUTPUT with the AM ALC turned off, measure $V_{off}$ first:
Remove any signal at the RF INPUT and connect a dc voltmeter to AM OUTPUT.

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>AUTOMATIC OPERATION</th>
<th>57Z</th>
<th>INPUT FREQUENCY</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-15</td>
<td></td>
<td></td>
<td>AUMZ</td>
</tr>
</tbody>
</table>

For this example, assume the voltmeter reads an offset voltage of $-0.36$ Vdc. Connect an AM signal to the RF INPUT and tune the Modulation Analyzer. Disable the AM ALC by selecting 6.2 SPCL.

Measure the dc voltage at AM OUTPUT. (When low AM rates are used, it is easiest to measure the dc voltage at AM OUTPUT before the modulation is applied.) For this example, assume the voltmeter reads $-0.46$ Vdc. Measure the peak ac voltage at AM OUTPUT (for low rates an oscilloscope may be necessary). For this example, assume 0.02 Vpk was measured on an oscilloscope. The % AM is:

$$
\% AM = \frac{V_{pk} \times 100\%}{|V_{dc} - off|} = \frac{0.02 \times 100\%}{|(-0.46) - (-0.36)|} = 20\% AM
$$

BLOCK DIAGRAM

![AM Output Block Diagram](image)

AM Output Block Diagram
COMMENTS

Inherent IF Component

AM OUTPUT contains a significant IF component which is greatest when operating at a carrier frequency of 150 kHz.

RF Peak Detector Measurements of AM Output

The accuracy of measurements made on the AM OUTPUT signal could be degraded if RF level measurements are made using the RF peak detector (Special Function 35.0).
FUNCTIONS

FM, Special Function 2 (Audio Range)

DESCRIPTION

The Modulation Analyzer can measure the FM deviation of the tuned input signal. (Special Function 2 enables the instrument to set limits on the range of FM deviation that can be measured.) FM Measurements are specified for rates from 20 Hz to 10 kHz for carrier frequencies 10 MHz and below (or whenever the 455 kHz IF is used) and from 20 Hz to 200 kHz for carrier frequencies from 10 to 1300 MHz (1.5 MHz IF only). The corresponding 3 dB audio bandwidths are approximately 0.5 Hz to 15 kHz for carriers 10 MHz and below (or with the 455 kHz IF) and approximately 0.2 Hz to 260 kHz for carriers from 10 to 1300 MHz (1.5 MHz IF only). Peak deviations up to 40 kHz can be measured on carriers below 10 MHz, and peak deviations up to 400 kHz can be measured on carriers above 10 MHz.

The demodulated signal’s frequency and distortion can also be measured. (Refer to Audio Measurements on page 3–197.)

PROCEDURE

To make an FM measurement, first tune the instrument to the input signal by selecting Automatic Operation. Press the FM key.

Select an audio detector: PEAK+, PEAK−, PEAK±/2, AVG, or RMS. (The RMS detector, selected by pressing the Blue Key and AVG key, is accurate in measuring FM, has a reduced bandwidth, and is usually only used for less audio distortion measurements.)
The following table lists the different measurement range limits that can be selected with Special Function 2:

<table>
<thead>
<tr>
<th>Modulation Range (Peak kHz dev.)</th>
<th>Detector Selected</th>
<th>Special Function Code</th>
<th>Program Code</th>
<th>Display Resolution (Hz)</th>

¹ With 750 μs de-emphasis, pre-display only.

To filter the demodulated signal, press the appropriate filter keys. (Refer to Audio Filters, on page 3–179 for more information about filters.) If de-emphasis equalization is desired, select the appropriate time constant and display placement. (Refer to FM De-emphasis on page 3–159 for more information about filters.)

**EXAMPLE**

To measure the positive peak deviation of a signal in a 50 Hz to 15 kHz post-detection bandwidth and to place a 750 μs time constant de-emphasis before the display:

---

### LOCAL (keystrokes)

- MEASUREMENT: FM
- DETECTOR: PEAK
- FILTERS: 30 Hz, 15 kHz
- FM DE-EMPHASIS: 750 μs

### HP (B) (program codes)

- Measurement
- Detector
- Filters
- M2 D1 H1 L2 P1 P5
- FM De-emphasis

---

3–152 FM
HP-IB PROGRAM CODES

All HP-IB codes for setting range limits for FM measurements are provided in "Procedures".

FM = M2
SPCL = SP

MEASUREMENT TECHNIQUE

The FM on the IF is demodulated by a frequency discriminator. The amplitude of the discriminator's output is proportional to the frequency deviation. The demodulated signal is filtered, audio detected, and displayed as kHz deviation.

FM de-emphasis equalization can be inserted ahead of the audio detectors and display circuitry by selecting PRE DISPLAY. The demodulated FM signal always passes through the FM de-emphasis "network" before it appears at the output of MODULATION OUTPUT/AUDIO INPUT.

![FM Measurement Block Diagram](image)

COMMENTS

Input/Output Status

The demodulated FM is present at MODULATION OUTPUT/AUDIO INPUT (unless AUDIO INPUT has been selected). The demodulated FM is usually present at the rear-panel FM OUTPUT connector. If the RF input signal drops too low for accurate FM demodulation, the FM measurement is automatically squelched (muted, turned off) except for the FM OUTPUT. (Refer to FM Output on page 3-163.)

Relative FM Deviation Measurements

If FM deviation is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3-215.)

FM 3-153
Peak±/2 Detector

The PEAK+ detector always detects the upward carrier frequency excursion while the PEAK– detector always detects the downward carrier frequency excursion. The PEAK±/2 detector sums the upward and downward frequency-exursion readings and divides the total by two to provide an average of the two peak values. (Do not confuse this "average" value with the detected average value.)

Inverted Output Signals

When operating with carrier frequencies below 2.5 MHz, the output signal at MODULATION OUTPUT/AUDIO INPUT is inverted unless the 455 kHz IF is selected. When operating with carrier frequencies above 2.5 MHz or when using the 455 kHz IF, the signal at FM OUTPUT is inverted.

Automatic Range Selection

The routine which automatically selects the modulation range contains regions of overlap between the following displayed peak deviations:

0.35 and 0.4 kHz (750 μs de-emphasis, pre-display only), 3.5 and 4 kHz, and 35 and 40 kHz.

When using the average or RMS detector, ranging will occur at readings lower than these. In general, if the modulation is reduced from a higher range into an overlap region, the range does not change. To range the display for increased resolution, press the FM key a second time. To set the instrument to a selected modulation range, refer to Audio Range.

Default Condition

When the Modulation Analyzer is first powered up, demodulated FM, with a sensitivity of 0.01 Vpk/MHz (400 kHz peak deviation range), is available at MODULATION OUTPUT/AUDIO INPUT. The instrument does not autorange to more sensitive ranges because the Frequency Measurement mode has been automatically selected, which automatically disables Error 04 (audio circuits overdriven). When Error 04 is disabled, the instrument only autoranges to less sensitive audio ranges.

Increased Accuracy

Accuracy of FM readings may be improved by using the FM Calibrator (refer to FM Calibration on page 3–155) and by taking into account the effects of residual noise (refer to Residual Noise Effects on page 3–191).

Automatic Squelching

If the RF input signal drops too low for accurate FM demodulation, the FM measurement is automatically squelched (muted, turned off).

Potential Inaccuracies

AM conditions that cause the carrier signal to disappear (such as 100% AM or pulse modulation) will cause inaccuracies in measurement of FM, ΦM, or input frequency, or they could cause Error 05 (FM squelched) to be displayed when these measurements are selected.

Considerations When Using the RMS Detector

During FM measurements if the RMS detector is selected (Blue Key, AVG), FM de-emphasis pre-display is automatically selected. Pre-display must turn on at this time due to circuit configuration of the Modulation Analyzer. When pre-display is selected this way, it will not turn off automatically when another detector is selected. Turn off pre-display (after selecting another detector) by pressing the PRE DISPLAY key (HP-IB code: P0). Measurements could be affected by this pre-display selection.
FM Calibration

FUNCTIONS
CALIBRATE, SAVE CAL, Function 12 (FM Calibration), Special Function 17 (FM Calibration Factor)

DESCRIPTION
The accuracy of the Modulation Analyzer's FM demodulator can be checked with the internal FM calibrator. The calibration process generates a calibration factor to compensate for the FM measurement error (within the accuracy limits of the FM Calibrator). The calibration factor can then be enabled to automatically correct the measured FM error in subsequent measurements using the SAVE CAL key or Special Function 17. With the calibration factor enabled, FM measurements can be made with an accuracy typically better than 0.5%. The calibration factor can be enabled, disabled, or displayed at any time.

Other instruments in the HP 8901 and 8902 RF signal analyzer family can be calibrated or cross checked with the Modulation Analyzer's FM calibrator using Special Function 12.

PROCEDURE

Self-Calibration
To determine the measurement error of the Modulation Analyzer's FM demodulation circuits, first allow at least a half-hour continuous operation before calibration, then perform the following steps:

1. Connect the CALIBRATION AM/FM OUTPUT to the RF INPUT with a 50Ω cable (or a sensor module with an internal switch such as the HP 11722A) and select FM.
2. Press the CALIBRATE key. After several seconds, the FM calibration factor is displayed in % and stored (but not enabled unless already enabled).

The instrument displays 100.00% if no error is measured. A display of 100.17% means the FM demodulator in the Modulation Analyzer is reading 0.17% high. As long as the CALIBRATE key light is on and the cable is connected, calibration repeats and the FM calibration factor is updated approximately every 17 seconds. To turn off the calibrator, select CALIBRATE or any Measurement key.

NOTE
For optimum accuracy, the instrument should be continuously operating for at least one half hour before calibration is performed. In addition, the first two FM Calibration Factors received after instrument power-up should not be used even if the instrument is already warm, since the circuits in the audio chain may not be fully settled.

Correcting Measurements with the FM Calibration Factor
Once a calibration factor has been determined, the instrument retains that value in its non-volatile memory. This factor can be enabled to automatically correct FM measurements. The calibration factor can also be disabled or displayed.

Selecting % CAL FACTOR (Blue Key, MHz) or 16.2 SPCL displays the Calibration Factor being used.
Enter the appropriate front-panel key or special function code to manipulate the FM Calibration Factor as described in the following table:

<table>

Calibrating or Cross Checking Another HP 8901 or 8902 RF Signal Analyzer

To compute an FM calibration factor for another RF signal analyzer that has no internal calibrator, or that has an internal calibrator that is to be cross checked, use the Modulation Analyzer and its calibrator as follows:

1. Connect the Modulation Analyzer's CALIBRATION AM/FM OUTPUT to the RF input of the other RF signal analyzer.

2. Key in 12.0 SPCL into the Modulation Analyzer. Record the value that appears in the display. This is the computed, calibrated, peak FM deviation (excluding noise).

3. Key in 12.1 SPCL into both instruments. Record the value that appears on the display of the RF signal analyzer. (If display jitter makes readings difficult, key in 5.1 SPCL.) The displayed value is the weighted, peak, residual FM deviation of the calibrator's unmodulated output as demodulated by the RF signal analyzer.

4. Key in 12.2 SPCL for both instruments. Record the value that appears on the display of the RF signal analyzer. (If display jitter makes readings difficult, select 5.1 SPCL.) The displayed value is the demodulated, positive, peak FM deviation of the calibrator's modulated output (including noise).

5. On the RF signal analyzer, select PEAK-. Note the value displayed on the RF signal analyzer. If the difference between the results of steps 4 and 5 is three counts or less in the least significant digit, an average between the two need not be computed; use the result from step 4. If the difference between the two readings is greater than three counts in the least significant digit, compute the average as follows:

\[
(12.2\text{ result}) = \frac{(\text{result of step 4}) + (\text{result of step 5})}{2}
\]

6. Compute the FM calibration factor of the RF signal analyzer as follows:

\[
FM\ \text{Calibration Factor}\ (%) = 100 \times \frac{(12.2\text{ result}) - (12.1\text{ result})}{(12.0\text{ result})}
\]

7. To use this FM calibration factor to correct FM measurements made with the RF signal analyzer, enter the value as a ratio reference and use the Ratio function in the RF signal analyzer.
The Special Function codes are summarized in the table below:

<table>
<thead>
<tr>
<th>Function</th>
<th>Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display computed peak FM</td>

</tr>
<tr>
<td>Display demodulated peak FM</td>
<td>12.2 SPCL</td>
<td>12.2SP</td>
</tr>
</tbody>
</table>

**HP-IB PROGRAM CODES**

HP-IB codes for enabling, disabling, or displaying the internal FM calibration factor are provided in "Procedures". The HP-IB codes for the FM Calibrator Special Function used to calibrate another RF signal analyzer are also provided as part of "Procedures".

FM = M2  
CALIBRATE on = C1  
CALIBRATE off = C0  
SPCL = SP

**INDICATIONS**

**Self-Calibration**

When the CALIBRATE key is pressed, approximately 17 seconds pass during which the instrument configures itself and tunes to the calibrator’s signal. The display indicates four dashes (-----) and lights the % annunciator. Once the FM Calibration Factor has been computed, it is displayed. Subsequent updates occur approximately every 17 seconds.

**Correcting Measurements with the FM Calibration Factor (Self-Calibrated)**

When the calibration factor is enabled, the FM deviation measurement is always a corrected measurement.

If % CAL FACTOR is selected, and the FM calibration factor is enabled, the FM calibration factor is displayed. If % CAL FACTOR is selected, and the FM calibration factor is disabled, 100% is displayed. (Note the resolution of 1%.)

**Calibrating Another RF Signal Analyzer**

The Modulation Analyzer displays the computed FM deviation (Special Function 12.0), but shows two dashes (--) throughout the rest of the procedure.

**MEASUREMENT TECHNIQUE**

When FM is selected and CALIBRATE is selected, a 10.1 MHz voltage controlled oscillator (VCO) within the calibrator is driven to one end of its nominal tuning range. The frequency of the VCO is counted, and the oscillator is driven to the opposite end of its tuning range where it is counted again. The peak FM deviation is computed from these measurements.

While the VCO is at one end of its range, the residual FM of the calibrator (very low) and the FM Demodulator (more significant) are characterized and weighted. (Refer to Residual Noise Effects on page 3–191.) The VCO is frequency modulated by a 10 kHz modulation oscillator, and the FM
The Modulation Analyzer compares the deviation (static measurements) with the demodulated FM (toggled measurements) and computes its accuracy error as follows:

\[
FM\ Calibration\ Factor\ (\%) = \frac{Demodulated\ FM - Demodulated\ Residual\ FM}{Computed\ FM} \times 100
\]

All segments of the calibration are carefully monitored. If any segment is out of limits, the calibration is aborted and Error 08 is displayed.

**Simplified Block Diagram of the FM Calibrator**

**COMMENTS**

**Default Calibration Factor**

If the instrument’s non-volatile memory is erased, 100.00% is used as the default calibration factor.

**Updating the FM Calibration Factor**

Whenever FM calibration is performed, the instrument updates the stored FM calibration factor.

**Special Function Cancellation**

Performing calibration cancels most Special Functions.

**When Using the FM Calibrator to Calibrate Other Signal Analyzers**

The modulation waveform of the FM Calibrator is a rounded trapezoid. An signal analyzer, which uses it as a calibration standard, must have demodulation and audio processing circuits which preserve the full fidelity of the waveform.

**Automatic FM Ranging**

When used to calibrate an RF signal analyzer, Special Functions 12.1 and 12.2 set the FM deviation range to that of 0 to 40 kHz (Special Function 2.2). Upon exiting the FM Calibrator Special Function, the audio ranging is not returned to automatic but remains fixed (thus leaving the SPCL light on). Key in 2.0 SPCL to return the audio ranging to automatic.
**FUNCTIONS**

Pre-Display, 25μs, 50μs, 75μs, 750μs

**DESCRIPTION**

The de-emphasis networks equalize the pre-emphasis often encoded on broadcast FM signals. This type of equalization provides a simple means of reducing audible noise on FM communication systems. Pre-emphasis gives a 6 dB per octave, high-frequency boost to the baseband audio before modulating the carrier. De-emphasis reverses the boost after demodulation at the receiver. The 3 dB corner of the pre-emphasis or de-emphasis network is usually expressed as a time constant. The relationship between the time constant, \( \tau_0 \), and the 3dB corner frequency, \( f_o \), is \( f_o = \frac{1}{2\pi \tau_0} \).

The 3dB corner frequencies of the de-emphasis equalizers (typically accurate to ±3%) are listed in the following table:

<table>
<thead>
<tr>
<th>Time Constant (μs)</th>
<th>3 dB Frequency (Hz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>6366</td>
</tr>
<tr>
<td>50</td>
<td>3183</td>
</tr>
<tr>
<td>75</td>
<td>2122</td>
</tr>
<tr>
<td>750</td>
<td>212.2</td>
</tr>
</tbody>
</table>

**PROCEDURE**

To add de-emphasis to the demodulated FM, select the key corresponding to the desired time constant. (Unless AUDIO INPUT has been selected, the de-emphasized FM is available at the MODULATION OUTPUT/AUDIO INPUT.) To also display the de-emphasized FM, select PRE DISPLAY.

**HP-IB**

In local operation, to turn off one of the de-emphasis functions, press the lighted key a second time. In remote operation, turn the equalizers off with code PO. (HP-IB code PO also turns off the PRE DISPLAY function.)
EXAMPLE

To measure the positive peak FM deviation of a carrier with 750 µs de-emphasis inserted before the deviation measurement:

<table>

COMMENTS

Input/Output Status.

When selected, the de-emphasis networks are inserted in the audio signal path following the audio filters. They will affect the output signal at MODULATION OUTPUT/AUDIO INPUT and can be placed before the audio detector and display. (Refer to the block diagram in FM.) De-emphasis has no affect on the rear panel FM Output.

When Measuring Low Deviation FM

When 750 µs de-emphasis is selected, FM sensitivity at the MODULATION OUTPUT/AUDIO INPUT is increased by a factor of ten. The range of deviation measurements is restricted to 40 kHz peak deviation or less after de-emphasis. The display resolution, however, remains the same as without de-emphasis unless the pre-display mode has been selected at which time the display resolution increases ten times. This feature provides greater resolution for measuring low deviation FM.
**HP-IB. Automatic Selection of Pre-Display.**

When the true rms detector is selected, the pre-display mode for FM de-emphasis is automatically enabled. This is true whether FM has been selected or not. (Selection of the FM de-emphasis time constant, however, remains unaffected.) The pre-display mode remains enabled until deliberately disabled. This idiosyncrasy is important to remember when programming the instrument via HP-IB.

**Considerations When Using the RMS Detector**

During FM measurements if the RMS detector is selected (Blue Key, AVG), FM de-emphasis pre-display is automatically selected. Pre-display must turn on at this time due to circuit configuration of the Modulation Analyzer. When pre-display is selected this way, it will not turn off automatically when another detector is selected. Turn off pre-display (after selecting another detector) by pressing the PRE DISPLAY key (HP-IB code: P0). Measurements could be affected by this pre-display selection.
FM Output

CAUTION

Do not apply greater than 10 Vpk (ac + dc) into the rear-panel FM OUTPUT connector or damage to the instrument may result.

DESCRIPTION

The rear-panel FM OUTPUT (dc-coupled, 10 kΩ output impedance) provides an auxiliary output for the FM demodulated from the RF input signal. This output enables monitoring of FM during display of other measurements (such as AM, φM, or audio signals) or when the modulation rate is very low.

The output signal comprises both a dc voltage, related to the counted IF frequency, and an ac voltage (bandwidth 16 kHz, one pole) proportional to the FM deviation.

With the input signal centered in the IF, the nominal dc offset voltage at FM OUTPUT is approximately 0.8 Vdc for the 1.5 MHz IF and −5.6 Vdc for the 455 kHz IF. The FM sensitivity is typically 6 V/MHz or 6 mV/kHz. The dc voltage at FM OUTPUT can be calculated as follows:

\[ V_{dc} = V_{off} - \frac{K \times (FREQ\ ERROR)}{1000} \]

where: \( V_{dc} \) = representation of the dc voltage at FM OUTPUT volts, 
\( V_{off} \) = representation of the dc offset voltage for the IF used volts, 
\( K \) = the FM sensitivity in mV/kHz, or V/MHz, and 
FREQ ERROR = the kHz error displayed when FREQ ERROR is selected.

Measure \( V_{off} \) when the frequency error is 0 kHz. The sensitivity can be measured using the following procedure:

PROCEDURE

To determine the sensitivity of the FM OUTPUT, apply an unmodulated 2 MHz carrier at the RF INPUT. (Select 3.2 SPCL, which uses the 1.5 MHz IF described in Filters, RF and IF on page 3–229.) Measure the dc voltage at the output with a dc voltmeter. Move the carrier to 1 MHz and again note the dc voltage. The FM sensitivity \( (K) \) in V/MHz or mV/kHz is:

\[ K = (V_{dc} \pm 2 \text{ MHz}) - (V_{dc} \pm 1 \text{ MHz}) \]

EXAMPLE

A 2 MHz unmodulated signal is applied to the RF INPUT. A dc voltmeter connected to FM OUTPUT measures +3.89 Vdc. When the carrier is set to 1 MHz, −2.272 Vdc is measured. The FM sensitivity is:

\[ (3.890) - (-2.272) = 6.162 \text{ V/MHz or 6.162 mV/kHz} \]
**BLOCK DIAGRAM**

![FM Output Block Diagram](image)

**COMMENTS**

**Inherent IF Component**

FM OUTPUT is unsquelched and also contains a significant component at twice the IF frequency which is greatest when operating at a carrier frequency of 150 kHz.

**Inverted AC Output Component**

Note that the sense of the ac output component (corresponding to the demodulated FM) is inverted for carriers above 2.5 MHz.

**Accuracy of Output During RF Level Measurements**

When RF Level measurements (Special Function 35) are made, automatic selection of RF input attenuation overrides any manual settings that might have been selected with Special Function 1. The selected attenuation could degrade the accuracy of measurements made on the FM OUTPUT signal.
Tone-Burst Receiver

FUNCTIONS
Special Function 18 (Tone-Burst Receiver)

DESCRIPTION
In some FM applications (mobile radio testing, for example), after a transmitter is keyed, it issues squelch tones for a brief interval. Often, it is necessary to measure the frequency of the squelch tones. This measurement is made difficult by the noise in the demodulated audio during the short delay between the keying of the transmitter and the appearance of the audio tones.

Special Function 18 enables the Modulation Analyzer to be configured as a tone-burst receiver. This function inserts a user-selectable delay between the instant the instrument senses an RF signal at its RF INPUT and the time when it turns on the output of MODULATION OUTPUT/AUDIO INPUT. When an external counter is connected to this output, the squelch tone will reach the counter only when a valid measurement can be made. The time delay is selectable from 1 through 99 milliseconds. The following photo illustrates a 99 ms delay between transmitter keying (lower trace).

Oscilloscope Photo Depicting a 99 ms Delay Between Transmitter Keying Pulse (Lower Trace) and Activation of MODULATION OUTPUT/AUDIO INPUT
PROCEDURE

In order to successfully measure tone bursts, tune and range the Modulation Analyzer:

1. Select FM.
2. Select an audio detector and if desired, audio filters and FM de-emphasis.
3. Key on the transmitter and allow the Modulation Analyzer to range and tune automatically.
4. Select RANGE HOLD to hold all ranges and tuning.
5. Select the time delay to be inserted between the moment the transmitter is keyed and the time MODULATION OUTPUT/AUDIO INPUT is to be turned on. This delay becomes the Special Function suffix. (If 18.0 SPCL is selected, the Modulation Analyzer executes a 99 ms delay.)
6. Enter the Special Function code 18.NN (where NN is the selected delay in milliseconds), then select SPCL. (If 18.5 is entered, a 5 ms delay is executed. For a 50 ms delay, enter 18.50.)

The Modulation Analyzer is now initiated to receive tone bursts. To exit this mode, select any key except the Blue Key, S (shift), or LOCAL Key, or numeric keys.

PROGRAM CODES

The Special Function code suffix is derived from the time delay as described in “PROCEDURE”.

SPCL = SP

INDICATIONS

As the numeric code is entered, it appears on the front panel display. When the SPCL key is pressed, 18.NN is displayed (NN is the delay in milliseconds). If no RF is at the RF INPUT connector, two dashes (—) are displayed.

COMMENTS

Suggested Use of Maximum Delay

When using the Tune Burst Receiver Special Function, use the 99 ms delay for best results. Shorter delays require very careful setup since, with no input, the high-gain IF Amplifier and Limiters "tune" the noise to an average frequency often slightly different than the nominal IF. When RF first enters the instrument, the IF shifts abruptly to the nominal frequency. This shift creates an FM transient which settles out after a short period and thus is not apparent with longer delays. With short delays the transients can be avoided by carefully tuning the instrument so that the IF frequency when the transmitter is on is close to, or equal to, the average IF frequency when the transmitter is off.

HP-IB

This function is best used when operating via HP-IB since the external counter connected to the output of MODULATION OUTPUT/AUDIO INPUT may need to acquire several sets of data in rapid succession (when counting multiple tones, for example).

Selective Range Holding

Ranges can be held for this function using the individual Special Functions for each parameter instead of using the Range Hold key.

Default Condition

Special Function code 18.0 provides a 99 ms delay.
**Tone Burst Frequency Cannot Be Measured**

The audio frequency measurement mode cannot be used to measure the frequency of the tone burst.

**ΦM But Not AM**

This feature works also with the ΦM measurement mode but not AM.
FUNCTIONS

ΦM, Special Function 2 (Audio Range)

DESCRIPTION

The ΦM key enables the Modulation Analyzer to measure the phase deviation of the tuned input signal. The demodulated ΦM is present at MODULATION OUTPUT/AUDIO INPUT.

The ΦM measurement is specified only for RF carriers from 10 to 1300 MHz; however, ΦM measurements can be performed on carriers from 150 kHz to 10 MHz.

The ΦM measurement is only specified for modulation rates from 200 Hz to 20 kHz; however, the low frequency 3 dB limit is typically 7 Hz.

The following figure shows the display resolution for different combinations of peak phase deviation and modulation rate.

![Graph showing peak phase deviation resolution vs. modulation rate](image)

PROCEDURE

To make a ΦM measurement, first tune the instrument to the input signal by selecting AUTOMATIC OPERATION. Select ΦM.

Select an audio detector: PEAK+, PEAK-, PEAK ± /2, AVG, or RMS. (The RMS detector, selected by pressing the Blue Key and the RMS key, is less accurate in measuring ΦM and is typically only used for audio distortion measurements.)
The following table lists the different measurement range limits that can be selected with Special Function 2:

<table>
<thead>
<tr>
<th>Modulation Range (Peak ± rad. dev.)</th>

</tbody>
</table>

To filter the demodulated signal, select the appropriate filter keys. (Refer to Audio Filters on page 3-179 for more information about filters.)

**EXAMPLE**

To measure the positive-peak phase deviation of a signal in a 50 Hz to 15 kHz post-detection bandwidth:

**HP-IB PROGRAM CODE**

All HP-IB codes for setting range limits for ΦM measurements are provided in “Procedures”.

ΦM = M3

3-170 ΦM
MEASUREMENT TECHNIQUE

The $\Phi M$ on the IF is first demodulated by a frequency discriminator. The amplitude of the discriminator's output is proportional to the frequency deviation. The demodulated signal is filtered and passed through an integrator, which extracts the phase information. The integrator's output is detected and displayed as phase deviation in radians. The integrator's output is made available at the MODULATION OUTPUT/AUDIO INPUT.

**$\Phi M$ Measurement Block Diagram**

COMMENTS

Frequency and Distortion Measurements

The demodulated signal's frequency and distortion can also be measured. (Refer to Audio Measurements which begins on page 3–197.)

Relative Measurements

If $\Phi M$ deviation is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3–215.)

Peak Detector

The PEAK+ detector always detects the upward carrier phase excursion while the PEAK− detector always detects the downward carrier phase excursion. The PEAK±/2 detector sums the upward and downward phase-exursion readings and divides the total by two to provide an average of the two peak values. (Do not confuse this “average” value with the detected average value.)

Inverted Output Signals

When operating with carrier frequencies below 2.5 MHz, the output signal at MODULATION OUTPUT/AUDIO INPUT is inverted unless the 455 kHz IF is selected. When operating with carrier frequencies above 2.5 MHz or when using the 455 kHz IF, the upper limit of the modulation rate is that of the >20 kHz LP FILTER.
Automatic Range Selection

The routine which automatically selects the modulation range contains regions of overlap between the following displayed peak deviations:

0.35 and .4 radians, 3.5 and 4 radians, and 35 and 40 radians.

When using the average or RMS detector, ranging will occur at readings lower than these. In general, if the modulation is reduced from a higher range into an overlap region, the range does not change. To range the display for increased resolution, press the FM key a second time. To set the instrument to a selected modulation range, refer to Audio Range on page 3–183.

Potential Inaccuracies

AM depths approaching 100% cause the carrier to nearly disappear and may cause inaccurate measurement of FM deviation or Error 05 (FM squelched).

Input/Output Status

When FM is selected, the signal at the rear-panel FM OUTPUT still represents demodulated FM, not FM.

Increased Accuracy

Accuracy of FM readings may be improved by taking into account the effects of residual noise. (Refer to Residual Noise Effects on page 3–191.)

Phase Deviation in Degrees

To display phase deviation in degrees instead of radians, enter 1.745 as a ratio reference and select RATIO. (Refer to Ratio on page 3–215.)

Pulsed Phase Modulation

Pulsed phase modulation, such as phase shift keying, cannot be accurately demodulated or measured by the Modulation Analyzer.

Recommended Filter Selection

Because of the high sensitivity of the FM measurement to low-frequency audio (microphonics, hum, etc.), use of the 50 Hz or 300 Hz low-pass filter is recommended. (Neither is switched in automatically.)
Audio Detectors

FUNCTIONS
PEAK+, PEAK−, PEAK±/2, PEAK HOLD, AVG, RMS.

DESCRIPTION
The Modulation Analyzer provides three types of audio detectors: peak responding, average responding (rms calibrated), and true rms. These three detectors provide six modes of audio measurements:

- Positive Peak (PEAK+)
- Negative Peak (PEAK−)
- Average of Positive and Negative Peaks (PEAK+/2 mode)
- Positive or Negative Peak Hold (PEAK HOLD)
- Average (AVG:RMS Calibrated)
- True RMS (RMS)

The two peak detector keys, when pressed individually, select whether the positive peak or the negative peak of the demodulated signal is measured. When the two peak detector keys are pressed simultaneously (the PEAK±/2 mode), the positive and negative peaks are averaged according to the following equation:

$$\text{Peak Average} = \frac{(\text{Peak}+) + (\text{Peak}−)}{2}$$

Peak Hold detection is used in conjunction with positive or negative audio peak detector modes. This mode enables the instrument to hold and display indefinitely, the largest peak detected. This feature is useful for capturing the peak maximum of a modulation transient.

Average detection selects an average-responding detector that is calibrated to read the rms value of a sinewave.

True RMS detection selects a true rms detector to measure audio signals. Also, noise and residual measurements are best measured with the true rms detector. This detector is automatically selected and is the only one used with the external audio voltage measurement (Special Function 30), audio distortion measurement and the SINAD measurement (Special Function 29). Selection of this detector also affects the FM pre-display de-emphasis. (Refer to “COMMENTS”.)

Once selected, a detector remains unchanged and is automatically activated each time modulation measurements are made until another detector is selected (except for the true rms detector as discussed in the previous paragraph). (However, once it is automatically selected, the true rms detector remains active.)
PROCEDURE

When a modulation measurement is selected, a detector is automatically activated.

To obtain a peak detector, select either PEAK+ or PEAK−. Press both keys simultaneously to enable the peak-average (PEAK±/2) mode.

Peak hold is used only with the peak detectors. Selecting PEAK HOLD initiates the peak hold mode. To initiate another peak hold, press that key again. The display is now updated with the new peak. The peak hold feature does not operate in the peak-average mode.

To obtain the average-responding, rms-calibrated detector, select AVG.

To initiate the true rms measurement, select RMS (Blue Key, AVG). The true rms detector is selected automatically for the external audio level measurement (Special Function 30), audio distortion measurement, and SINAD measurement (Special Function 29).

COMMENTS

Input/Output Status

The signal at MODULATION OUTPUT/AUDIO INPUT, AM OUTPUT, or FM OUTPUT is not affected by the DETECTOR keys.

True RMS Detector

Only the true rms detector can be used for external audio level (Special Function 30) and for audio distortion measurement, and SINAD (Special Function 29.)

HP-IB Automatic Selection of Pre-Display

When the true rms detector is selected, the pre-display mode for FM de-emphasis is automatically enabled. This is true whether FM has been selected or not. (Selection of the FM de-emphasis time constant, however, remains unaffected.) The pre-display mode remains enabled until deliberately disabled. This idiosyncrasy is important to remember when programming the instrument via HP-IB.

Peak Detector's Response Time

A slower response time for the audio peak detectors can be selected with Special Function 5.1. (Refer to Audio Detector Response on page 3-177.)
**Peak Hold Mode**

When the peak hold mode is selected, the limited rise time of the peak detector circuitry can cause a slight measurement error for narrow, one-time modulation transients. To prevent this error, repeat the peak-generating process several times while leaving the peak hold mode active.

If PEAK HOLD is selected while the average or true rms detector mode is active, the detector will switch to the peak detector mode previously selected. If PEAK HOLD is selected while the peak-average (PEAK±/2) mode is active, the detector reverts to PEAK+ with PEAK HOLD.

**HP-IB**

In remote operation, new peak-hold cycles can only be initiated by code D3. Thus, if the instrument is in HP-IB Hold mode (code T1), issue code D3 to initiate a peak-hold cycle. Although the display cannot be updated when in HP-IB Hold, the peak is captured, stored and updated. Upon leaving HP-IB hold via the triggering codes (T2 or T3), the data output represents the greatest peak captured since the peak-hold cycle was initiated.
Audio Detector Response

FUNCTIONS
Special Function 5 (Audio Detector Response)

DESCRIPTION
When making modulation measurements, both the audio peak detector response (for peak measurements including SINAD)\(^1\) and the digital averaging response (for rms measurements) are usually fast. A slower response time (narrower detection bandwidth) can be enabled using Special Function 5.1.

The slow response time improves measurement readability on unstable or noisy signals whenever display jitter is excessive.

PROCEDURE
The Modulation Analyzer is normally set for fast response. To change from fast to slow or vice versa, enter the corresponding Special Function code, then select SPCL.

<table>
<thead>
<tr>
<th>Audio Detector Response</th>
<th>Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fast</td>
<td>5.0 SPCL</td>
<td>5.0SP</td>
</tr>
<tr>
<td>Slow</td>
<td>5.1 SPCL</td>
<td>5.1SP</td>
</tr>
</tbody>
</table>

COMMENTS

Default Condition
When the instrument is first turned on or when Automatic Operation or Instrument Preset is selected, the response time returns to fast.

\(^1\) The slow response time for SINAD is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
Audio Filters

FUNCTIONS
HP FILTER, LP FILTER

DESCRIPTION
High-pass and low-pass filters can be inserted in the path of the demodulated signal.
The filters are used for such tasks as rejecting interfering audio signals such as line hum and sub-carriers.
They also provide pre-defined bandwidths for residual noise measurements.

PROCEDURE
Insert the desired demodulated signal filter by selecting the appropriate keys. Only one high-pass and
one low-pass filter can be inserted at once.
To remove a filter, select the key again.
To select a different filter, press the key corresponding to the desired filter.

HP-IB codes for the various filter keys (listed in the following table) only insert the filters. To remove a
high-pass or low-pass filter via HP-IB, use code H0 or L0 (respectively), or select another filter.

FILTER SELECTION AFFECTS MODULATION OUTPUT

The selected filters are always in the path of the demodulated signal independent of the selection of a modulation measurement. Thus, unless turned off, the output of MODULATION OUTPUT/AUDIO INPUT is filtered. In addition, the selected filters remain in effect when switching between modulation measurements.

AUTOMATIC FILTER SELECTION

Under certain conditions, filters are inserted automatically. When the 455 kHz IF is used, or when the RF input is less than 2.5 MHz, the 15 kHz low-pass filter is inserted unless another low-pass filter has been selected. (The ALL OFF >200 kHz low-pass filtering cannot be selected.) The 15 kHz low-pass filter selected when operating with the 455 kHz IF is automatically turned off when the 1.5 MHz IF is selected.

BANDWIDTH LIMITATIONS

With no filters selected, the post-demodulation bandwidth is from less than 20 Hz to greater than 200 kHz. (These frequencies refer to the limits over which measurement accuracy is specified, not the 3 dB bandwidth.) However, the IF circuits and demodulators impose more severe bandwidth limits. Refer to each specific measurement in these Detailed Operating Instructions for bandwidth limitations.
Filter Characteristics

The individual filter characteristics are given below. The 3 dB bandwidth is specified in the filter's designation and is typically accurate to ±3%.

High-Pass Filters:

50 Hz High Pass: Two-pole Butterworth, 1% flat to <200 Hz
300 Hz High Pass: Two-pole Butterworth, 1% flat to <1 kHz

Low-Pass Filters:

3 kHz Low Pass: Five-pole Butterworth, 1% flat to >1 kHz
15 kHz Low Pass: Five-pole Chebyshev, 1% flat to >10 kHz
>20 kHz Low Pass: Nine-pole Bessel, 1% flat to >10 kHz. (When used with square wave modulation, this filter typically overshoots <1%. This filter's 3 dB point is typically 110 kHz.)

Filter Selection Does Not Affect Some Measurements

External Audio level, distortion, and SINAD measurements are unaffected by the audio filters.

Recommended Filter Selection

Because of the high sensitivity of the FM measurement to low-frequency audio (microphonics, hum, etc.), use of the 50 Hz or 300 Hz low-pass filter is recommended. (Neither is switched in automatically.)
Audio Range

FUNCTIONS

Special Function 2 (Audio Range)

DESCRIPTION

The Modulation Analyzer is usually set to automatically select the audio range appropriate for the desired measurement. To set the audio range manually, use Special Function 2.

PROCEDURE

To set the audio range or to re-enter the automatic selection mode, select the corresponding Special Function code.

COMMENTS

Audio Range Effect on Distortion Measurements

The selected Audio Range has no effect on audio distortion or SINAD measurements.

When the audio range selected is too high for the level of the audio signal, the signal-to-noise ratio will be low (no error is generated). (The output of MODULATION OUTPUT/AUDIO INPUT tracks the displayed values.) When the audio range is too low for the audio signal level, Error 04 is generated. (The output of the MODULATION OUTPUT/AUDIO INPUT will probably be clipped.) Depending on the audio filtering and detector in use, Error 04 may not be generated at exactly the nominal values listed in the tables above.

Disabling Error 04 Inhibits Audio Autoranging

When Error 04 is disabled (refer to Error Message Disable Control on page 3-233), the Modulation Analyzer automatically ranges to a less sensitive range when the signal level requires, but it does not range back when the audio level is reduced. This feature is used most often when modulation varies widely with time (such as off-the-air demodulation of a broadcast signal).
Modulation Output/Audio Input

FUNCTIONS

AUDI O INPUT

CAUTION
Do not apply greater than 10 Vdc or greater than +30 dBm (1 watt) into MODULATION OUTPUT/AUDIO INPUT or damage to the instrument may result.

NOTE
For optimum signal flatness, cables attached to MODULATION OUTPUT/AUDIO INPUT (when used as an output) should be terminated in 600Ω.

DESCRIPTION

Modulation Output

MODULATION OUTPUT/AUDIO INPUT provides a calibrated output for signals demodulated by the Modulation Analyzer. The output signal available at the connector usually corresponds to the current modulation measurement. (The output is dc coupled and has a 600Ω output impedance into a BNC female connector.)

Audio Input

The input at MODULATION OUTPUT/AUDIO INPUT also provides external access to the audio measurement circuits. The input impedance at the connector is 100 kΩ.
Effects on Modulation Output/Audio Input During Measurements

Measurements have a direct effect on MODULATION OUTPUT/AUDIO INPUT. The following table lists the functioning of the MODULATION OUTPUT/AUDIO INPUT for each measurement. (Measurements not listed have no effect.)

<table>
<thead>

HP and LP Filters, and FM De-emphasis affect the output, but not the input of MODULATION OUTPUT/AUDIO INPUT. (See the Modulation Output/Audio Input Block Diagram in this instruction.)
Display Resolution vs. Modulation Output Sensitivity

In Automatic Operation, when the Modulation Output/Audio Input feature is used, the output autoranges. Autoranging usually occurs between 3.5 and 4 Vpk, open circuit. Many variables, however, affect the autorange limits and hence the displayed measurement resolution. The variables include: type of modulation, audio detector, audio filtering, and FM de-emphasis. Special Function 2 permits manual setting of the audio range.

The following table examines this relationship. (Refer to Audio Range on page 3-183 for more information on modulation ranges.)

*Available only with 750 μs de-emphasis, pre-display.

BLOCK DIAGRAM

Modulation Output/Audio Input Block Diagram
FUNCTIONS THAT OVERRIDE AUDIO INPUT

The Audio Input function is overridden by all measurements except audio frequency, distortion, SINAD, and external level.

ERRORS DISABLE OUTPUT SIGNAL

Errors 01 through 03, 05, 10, and HP-IB Error 96 (corresponds to a display of two dashes) turn off the signal at MODULATION OUTPUT/AUDIO INPUT.

DEFAULT CONDITION

When the Modulation Analyzer is first powered up, the demodulated output signal at MODULATION OUTPUT/AUDIO INPUT is FM. The sensitivity is 0.01 mV/Hz (the least-sensitive range) and will not autorange to more sensitive ranges. This is because at power up, FREQ is selected. Thus Error 04 (audio circuits overdriven) is automatically disabled. When Error 04 is disabled, only autoranging to less-sensitive audio ranges is allowed.

SAFEGUARDING OUTPUT SIGNAL

When Errors 01 through 04 are always enabled via Special Function 8.8, the output signal at MODULATION OUTPUT/AUDIO INPUT is entirely safeguarded. Under this condition the instrument operates as a calibrated receiver and an error is displayed whenever the signal at MODULATION OUTPUT/AUDIO INPUT is uncalibrated. (Refer to Error Message Disable Control on page 3-233.)

FILTERS AFFECT OUTPUT SIGNAL

The audio high-pass and low-pass filters and FM de-emphasis affect the output but not the input of the MODULATION OUTPUT/AUDIO INPUT.
Residual Noise Effects

DESCRIPTION

To make the most accurate peak-modulation measurements, it is necessary to measure and correct the effects of residual noise, that is, noise not on the baseband signal, but modulating the RF carrier. The following procedure describes the measurement technique.

PROCEDURE

The following procedure enables the user to correct for the effects of residual noise on peak-modulation measurements.

NOTE

This procedure applies to sinewave modulation only.

1. Set up and make a normal peak-modulation measurement. The displayed measurement result will include the signal plus its noise, \((S + N)_{pk}\).
2. Press the Range Hold key to prevent autoranging. If filtering and/or de-emphasis was used in step 1, make all the following measurements with the same settings.
3. Remove the modulation from the signal and measure the remaining peak-residual noise, \(N_{pk}\), on the carrier.
4. Select AVG. Measure the average residual noise, \(N_{av}\).
5. Compute

\[
\frac{(S + N)_{pk}}{N_{pk}} \text{ and } \frac{N_{pk}}{N_{av}}
\]

6. Use the following nomograph to determine the percent, \(N\%\), of the peak-residual noise level, \(N_{pk}\), to be subtracted from the original, peak-signal-plus-noise measurement, \((S + N)_{pk}\).
7. Compute the corrected, peak modulation

\[
S_{pk} = (S + N)_{pk} - N_{pk}(N\%) 
\]

where \(N\%\) is expressed as a ratio (rather than in \%).
Nomograph for Calculating Percentage of $N_{pk}$ to be Subtracted from $(S + N)_{pk}$ to obtain $S_{pk}$ (Sinewave Modulation Only)

**EXAMPLE**

An RF signal is applied to the Modulation Analyzer. The modulation rate is 1 kHz and the peak modulation is to be measured in a 15 kHz post-detection bandwidth. To measure the peak AM depth and correct for the effects of residual noise on the modulation:

1. Measure the peak modulation depth, $(S + N)_{pk}$:

<table>
<thead>
<tr>
<th>LOCAL (keystrkes)</th>
<th>AUTOMATIC OPERATION</th>
<th>MEASUREMENT AM</th>
<th>DETECTOR PEAK</th>
<th>FILTER 15 kHz</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-IB (program codes)</td>
<td>Measurement</td>
<td>AU M1 D1 L2</td>
<td>Detector</td>
<td>Filter</td>
</tr>
</tbody>
</table>

For the purposes of subsequent calculations, assume the displayed AM is 30.80%.
2. Disable auto-ranging by pressing the RANGE HOLD key:

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>RANGE HOLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-IB (program codes)</td>
<td>G1 Range Hold</td>
</tr>
</tbody>
</table>

3. On the RF signal source, switch the AM off. Measure the residual AM, $N_{pk}$, on the CW signal. For the purposes of subsequent calculations, assume 0.07% is read on the Modulation Analyzer's display.

4. Measure the average residual modulation:

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>RMS CAL AVG</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-IB (program codes)</td>
<td>D4 Detector</td>
</tr>
</tbody>
</table>

For the purposes of subsequent calculations, assume the displayed average residual AM is 0.02%.

5. Compute:

$$\frac{N_{pk}}{N_{av}} = \frac{0.07\%}{0.02\%} = 3.5\%$$

6. Compute:

$$\frac{(S + N)_{pk}}{N_{pk}} = \frac{30.80\%}{0.07\%} = 440$$

7. Use the nomograph to find N%. (For the purposes of these calculations, assume N% is 26%.) Compute:

$$S_{pk} = (S + N)_{pk} - (N_{pk})(N\%) = 30.80\% - (0.07\%)(0.26) = 30.78\%.$$

**NOTE**

This correction factor of <0.1% of the peak reading is typical of a modulation measurement of a quality modulation source measured with the 15 kHz low-pass filter.
Residual noise is the short-term amplitude or phase (and thus frequency) instability inherent in any CW signal source. In a measurement system composed of a signal source and the Modulation Analyzer, residual noise is contributed by both instruments. When modulation is measured with the Modulation Analyzer, both the intended and residual combined are measured. To precisely determine the modulation index due to the baseband signal alone, the effects of residual noise must be factored out of the measurement results.

Two noise components are commonly encountered in modulation measurements: periodic (often line-related) and gaussian (random). Periodic noise and the baseband signal behave identically. The Modulation Analyzer measures the arithmetic sum of the peak or average levels of the two signals (according to the detector selected). To determine the modulation index due to the baseband signal alone, switch the modulation off, measure the peak-residual noise on the same range as before, and subtract the result from the original displayed modulation. The effects of random noise on the measurement system are not as straightforward. True random noise, when viewed in the frequency domain, is a continuous spectrum of frequencies at various amplitudes. The frequency of the noise spectrum is limited only by the bandwidths of the observing and/or generating devices. In the time domain, noise of this kind appears as random amplitude spikes (or fuzz) riding on top of the recovered baseband signal. The amplitude of these spikes is limited by the slow rate of the measuring and/or generating devices. Peak detecting these spikes exaggerates the amount of energy present in the noise spectrum so noise measurements are typically made with average-responding detectors and with limited bandwidths.

The measurement problem arises because modulation index is typically expressed as a peak level. To account for residual noise in these peak measurements, the actual effects of the noise on the Modulation Analyzer’s peak detector must be determined.

A simplified diagram of the Modulation Analyzer’s peak detector is shown in the following figure. Whenever the signal-plus-noise voltage into the comparator exceeds the voltage stored on the output capacitor, C, the comparator closes switch S1. The capacitor is then charged via the path from +V through resistor R. When the voltage across the capacitor exceeds the voltage of the incoming signal, the comparator opens the switch again. This process continues until the voltage on the capacitor is transferred to the voltmeter through the sample-and-hold switch, S2. C is then discharged by S3. When very narrow noise spikes are imposed on the comparator’s input, the charging circuit’s RC time constant will not allow the capacitor to fully charge before the noise peak has passed.
When noise alone is imposed on the detector, it is very probable that, as C begins to charge, a noise spike will exceed the voltage across the peak detector capacitor. However, as the voltage across the capacitor more nearly approaches the peak-noise level, this probability decreases. Thus the peak detector, over a significantly long time, can faithfully measure fairly high peak-noise levels.

When noise is riding on a sinewave, only the signal-plus-noise peaks exceeding the sinusoid’s peak level can add charge to the peak detector capacitor. Statistically, there is less chance that the composite input signal will exceed the voltage across the capacitor (already charged to the peak of the sinewave) when measuring a sinewave than when measuring only noise. Thus, the contribution of noise on the measured peak-modulation level decreases as the signal-to-noise ratio increases.¹ To simply measure the peak-residual noise present when the modulation is removed and subtract the result directly from the peak reading of the combined input, over-compensates the effects of the noise.

The effects of residual noise on the peak detector depend on the signal-to-noise ratio, the statistics of the noise spikes, and the response time of the specific peak detector. These effects are quantified by taking the ratio of the peak noise reading to the average noise reading. The average noise level is a truer measure of the actual amount of noise energy present, while the peak reading characterizes the peak detector and the statistics of the noise spikes.

COMMENTS

Noise Must Be Gaussian

The primary restriction placed on this method of accounting for residual noise is that the noise must be gaussian (that is, statistically random). Periodic noise (for example, line-related noise) has repeating peaks and thus does not fall within the statistical model used to derive the nomograph given in the procedure.

A noise-peak-to-noise-average ratio \(N_{pk}/N_{av}\) greater than 4.4 is a strong indication of a periodic component in the residual noise.

Use Range Hold During Measurement

Both the modulation and the noise measurements used with the nomograph should be made on the same modulation range and with the same peak-detector time-constant. Use the Range Hold key while the instrument is measuring the modulated carrier, then measure the residual noise.

Select the Highest of Successive Readings

When characterizing the effects of residual noise on peak \(\Phi M\) measurements using the 3 kHz low-pass filter, readings may jump considerably. Use the highest of 10 successive readings for all peak measurements in the computations. (Simply select PEAK HOLD and note the reading after 2 seconds.)

No Residual Noise in Calibration

The residual noise contributions of the AM and FM calibrators and the Modulation Analyzer are accounted for in the calibration procedures. It is not necessary to factor residual noise corrections into the calibration procedures described in this manual. (Refer to AM Calibration and FM Calibration.)

Considerations When Using the RMS Detector

During FM measurements if the RMS detector is selected (Blue Key, AVG), FM de-emphasis pre-display is automatically selected. Pre-display must turn on at this time due to circuit configuration of the Modulation Analyzer. When pre-display is selected this way, it will not turn off automatically when another detector is selected. Turn off pre-display (after selecting another detector) by pressing the PRE DISPLAY key (HP-IB code: P0). Measurements could be affected by this pre-display selection.

Audio Measurements Contents

AUDIO MEASUREMENTS

Audio Frequency ................................................................. 3-199
  • How to count the demodulated audio frequency.
  • How to count an external audio frequency.

Audio Distortion and Level .................................................. 3-201
  • How to measure audio distortion (only at 400 Hz or 1 kHz) on either an internally demodulated or an external audio input.
  • How to measure the level of external audio input.

SINAD ................................................................. 3-203
  • How to measure SINAD (only at 400 Hz or 1 kHz) on either an internally demodulated or an external audio input.
Audio Frequency

FUNCTIONS
AUDIO FREQ, AUDIO INPUT

DESCRIPTION
Audio Frequency counting can be performed on either demodulated internal signals or external audio signals as determined by the AUDIO INPUT key.

PROCEDURE
To count the frequency of the audio signal demodulated from the RF signal at the INPUT connector, select AUDIO FREQ (Shift, AM).

To count the frequency of an external audio signal at the MODULATION OUTPUT/AUDIO INPUT connector, follow the above procedure, and then select AUDIO INPUT. The measurement range is 20 Hz to 250 kHz. The input signal should not exceed 4 Vrms. The input impedance is approximately 100 kΩ.

HP-IB PROGRAM CODES
AUD FREQ = S1
AUD INPUT = A1

MEASUREMENT TECHNIQUE
The audio frequency is measured by a reciprocal-type counter. The input can be either the demodulated RF at the INPUT or an external audio input at the MODULATION OUTPUT/AUDIO INPUT. The Modulation Analyzer gates its internal 10 MHz time base reference with the audio input signal for at least 100 ms. The frequency is then determined by the following equation:

\[
audio \text{ frequency} = \frac{(\text{number of cycles of audio signal}) \times 10 \text{ MHz}}{\text{number of time base reference pulses}}
\]

The combination of minimum count time of 100 ms and the 10 MHz time base reference assures six-digit resolution.
The function of MODULATION OUTPUT/AUDIO INPUT connector is controlled by the AUDIO INPUT key. The connector has an input impedance of approximately 100 kΩ.

---

**COMMENTS**

**Relative Measurements**

If audio frequency is to be displayed relative to a reference, enter the value as a ratio reference using the Ratio function. (Refer to Ratio on page 3-215.)

**Finer Resolution for Frequencies from 100 to 250 kHz**

Special Function 32.1 enables a resolution of 0.1 Hz for frequencies 100 to 250 kHz. For dB measurements, this special function enables a resolution of 0.001 dB instead of the normally displayed resolution of 0.01 dB. The selection of Special Function 32.0 or 32.1 is maintained through instrument power down.

32.0 Audio frequency is displayed with the normal resolution of 1 Hz for frequencies from 100 to 250 kHz.

32.1 Audio frequency is displayed with a resolution of 0.1 Hz for frequencies from 100 to 250 kHz.

32.2 Displays 0 if the normal measurement resolution is enabled (32.0 SPCL) and displays 1 if a finer resolution is enabled (32.1 SPCL).

---

1 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
Audio Distortion and Level

FUNCTIONS

AUDIO DISTN, 1 kHz DISTN, 400 Hz DISTN, RMS, AUDIO INPUT, Special Function 30 (External Audio RMS Level)

DESCRIPTION

Measure distortion on either internally demodulated audio signals or externally input signals with fundamental frequencies of 1 kHz or 400 Hz. (The fundamental frequency must be within ±5% of the nominal 1 kHz or 400 Hz for accurate measurements.) Once selected, the measurement frequency remains unchanged and is automatically activated each time the audio distortion (or SINAD) measurement is selected.

Special Function 30.0 enables the instrument to measure the true rms level of an external signal applied to the MODULATION OUTPUT/AUDIO INPUT connector. (The connector is automatically switched to function as an input upon selection of Special Function 30.0. The true rms level of the internal demodulated audio cannot be measured.) Connector input impedance is nominally 100 kΩ. The maximum measurable input level is 4 V rms.

PROCEDURE

To measure distortion on the demodulated audio signal, select AUDIO DISTN (Shift, FM).

To measure distortion on an external audio signal applied to the MODULATION OUTPUT/AUDIO INPUT, select AUDIO DISTN (Shift, FM) and AUDIO INPUT. (Only the true rms detector can be used for these measurements.)

To change the measurement bandwidth of the internally demodulated audio signal, Select the desired filter keys. (Refer to Audio Filters on page 3-179.)

If measurements are to be made on a 1 kHz audio signal, select 1 kHz DISTN (Blue Key, PEAK+). If measurements are to be made on a 400 Hz audio signal, select 400 Hz DISTN (Blue Key, PEAK−).

To measure the true rms level of an audio signal applied to the MODULATION OUTPUT/AUDIO INPUT, select 30.0 SPCL.

HP-IB PROGRAM CODES

AUDIO DISTN=S2
AUDIO INPUT = A1
MODULATION OUTPUT = A0
1 kHz DISTN = D6
400 Hz DISTN = D6
LIN results = LN
LOG results = LG
mV units = MV
uV units = UV
VOLTS units = VL
SPCL = SP

MEASUREMENT TECHNIQUE

To measure audio distortion, the instrument compares the input signal level measurement made with a true rms detector to the same measurement made with the fundamental component removed. Total harmonic distortion is then calculated as the ratio of the signal with its fundamental removed to the unfiltered signal.
The broadband audio signal is first measured with a true rms detector; then the audio signal path is switched through a notch filter set to the fundamental frequency (1 kHz or 400 Hz). The notch filter has approximately 55 dB rejection at the notch frequency with 10% total bandwidth. The distortion is computed as the ratio of the signal from the output of the notch filter to the signal without filtering.

The function of the MODULATION OUTPUT/AUDIO INPUT is controlled by the AUDIO INPUT key. The connector has an impedance of approximately 100 kΩ when used as an input and 600Ω when used as an output.

The true rms level (from 0V to 4V) of any external audio signal (from 20 Hz to 40 kHz) can be measured using the same rms detector. (In this mode, the MODULATION OUTPUT/AUDIO INPUT connector always functions as an input.)

Auto Distortion and Level Block Diagram

COMMENTS

Audio Level Measurement in Watts

Selection of watts as the unit for audio level measurements results in an error.

Automatic Selection of RMS and PRE DISPLAY

Selection of an audio distortion or level measurement automatically selects the true rms audio detector and sets FM de-emphasis to the pre-display mode. (Refer to FM De-emphasis on page 3-159.)

The SINAD measurement mode (Special Function 29) is almost identical to the audio distortion measurement mode. SINAD, as measured by the instrument, is the reciprocal of distortion. (Refer to SINAD on page 3-203.)

Relative Measurements

If audio distortion or level are to be displayed relative to a reference, enter the value as a ratio reference by selecting RATIO. (Refer to Ratio on page 3-215.) The measured results can be displayed in either linear units (mV, %, etc.) or logarithmic units (dBV, dB, etc.) using the LOG/LIN key. The previously selected units are reinstated whenever an audio measurement is selected.
SINAD

FUNCTIONS

1 kHz DISTN, 400 Hz DISTN, Special Function 29 (SINAD)

DESCRIPTION

Special Function 29.0 enables the Modulation Analyzer to make SINAD (Signal to Noise And Distortion) measurements. The SINAD measurement is identical to the audio distortion measurement; but the result is expressed differently. SINAD is often measured as part of receiver sensitivity testing.

SINAD can be measured on audio signals with fundamental frequencies of either 1 kHz or 400 Hz using the 1 kHz DISTN or 400 Hz DISTN keys respectively. The fundamental frequency must be within ±5% of the nominal 1 kHz or 400 Hz for accurate measurements. Once selected, the measurement frequency remains unchanged and is automatically activated each time the SINAD (or audio distortion) measurement is selected.

SINAD can also be measured on an external audio signal applied to the MODULATION OUTPUT/AUDIO INPUT connector using the AUDIO INPUT key. When external audio is not selected, the instrument measures the SINAD on the internal demodulated audio.

PROCEDURE

To measure SINAD on the demodulated audio signal, select 29.0 SPCL.

To measure SINAD on an external audio signal applied to the MODULATION OUTPUT/AUDIO INPUT, select 29.0 SPCL and AUDIO INPUT. (Only the true rms detector can be used for this measurement.)

To change the measurement bandwidth of the internally demodulated audio signal, select the desired filter keys. (Refer to Audio Filters on page 3-179.)

If measurements are to be made on a 1 kHz signal, select 1 kHz DISTN (Blue Key, PEAK+). If measurements are to be made on a 400 Hz audio signal, select 400 Hz DISTN (Blue Key, PEAK-).

The measured results can be displayed in either linear units (%) or logarithmic units (dB) using the LOG/LIN key. The previously selected units are reinstated whenever an audio measurement is selected.

HP-IB PROGRAM CODES

AUDIO INPUT = A1
MODULATION OUTPUT = A0
1 kHz DISTN = D5
400 Hz DISTN = D6
LIN results = LN
LOG results = LG
SPCL = SP

MEASUREMENT TECHNIQUE

To measure SINAD, the instrument compares the input signal level measured by a true rms detector to the same measurement with the fundamental component removed. SINAD is then calculated as the ratio of the unfiltered signal to the signal with its fundamental removed. Refer to the measurement technique discussions in Audio Distortion and Level on page 3-201.
COMMENTS

Relative Measurements

If SINAD is to be displayed relative to a reference, enter the value as a ratio reference using the RATIO key. (Refer to Ratio on page 3–215.)

SINAD Response Time

A slower response time can be selected with Special Function 5.1.\(^1\) The slow response time improves measurement readability on unstable or noisy signals whenever display jitter is excessive.

\(^1\) The slow response time for SINAD is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
Additional Capabilities Contents

FUNCTIONS THAT CAN BE USED WITH MANY MEASUREMENTS

Automatic Operation ......................................................... 3–207
  • How to cancel special functions or automatically tune the instrument.
Instrument Preset ............................................................. 3–209
  • How to preset the instrument to its default state.
  • What the default conditions are.
Range Hold ........................................................................ 3–213
  • How to freeze current measurement ranges.
Ratio and Log/Lin ............................................................... 3–215
  • How to scale a measurement result to a reference in % or dB.
Limit ................................................................................... 3–219
  • How to set limits on measurements being made.
  • How overlimiting is displayed (front panel and HP-IB).
Store/Recall ....................................................................... 3–223
  • How to access the instrument’s 8 storage registers.

FUNCTIONS THAT INCREASE MEASUREMENT CAPABILITIES

Frequency Offset Control ................................................... 3–225
  • How to extend the frequency range of the instrument into the microwave region using an external down-converter.
Filters, RF and IF ............................................................... 3–229
  • How to insert the RF high-pass filter in the RF signal path to eliminate interfering, low-frequency signals.
  • How to select the frequency and bandwidth of the IF filters.
RF Input Attenuation ........................................................... 3–231
  • How to select RF input attenuation to eliminate input overload or to improve measurement sensitivity.
Error Message Disable Control ....................................... 3–233
  • How to disable or enable combinations of Errors 01 through 04 to extend the instrument’s usable measurement range.
Automatic Operation

FUNCTIONS

AUTOMATIC OPERATION

DESCRIPTION

The Automatic Operation function fulfills two major functions: (1) To configure the Modulation Analyzer to automatically tune to the largest detectable RF input signal and to make the selected measurement. (2) To cancel most special functions.

Specifically, Automatic Operation sets special functions with prefixes 1 through 10 to their 0-suffix state, cancels many special functions with prefixes greater than 10, and overrides all service special functions (prefixes 0, 40, or greater). (Refer to Special Functions on page 3-237 for details on special functions 1 through 39. Refer to Section 8 of the Service Manual for details on Service Special Functions.) Automatic Operation also cancels some front-panel settings (TRACK MODE, RANGE HOLD, and DISABLE ERROR).

Those features that are not affected by Automatic Operation include HP or LP FILTERs, FM DE-EMPHASIS, MEASUREMENT, CALIBRATION, DETECTOR, DISPLAY, and RATIO. RF level- and modulation-related calibration factors remain intact. Limit settings (Special Function 14) and Frequency Offset Control (Special Function 27) are also not affected.

PROCEDURE

To enter the Automatic Operation mode, select Automatic Operation. The instrument will immediately re-tune to the input signal and make the measurement selected.

HP-IB PROGRAM CODE

AUTOMATIC OPERATION = AU

COMMENTS

Input/Output Status

MODULATION OUTPUT/AUDIO INPUT is blanked temporarily during the automatic tuning process initiated by selecting Automatic Operation.

The Value of the Automatic Operation Capability

Automatic Operation is the easiest way to make measurements in applications where only a single carrier is present at the RF INPUT. The instrument configures itself to meet the needs of most measurement situations, and all error messages signaling inaccurate measurements are enabled.

Range Hold is Opposite to Automatic Operation

The converse of the Automatic Operation mode is the Range Hold function.

Restrictions on Entering Automatic Operation

The instrument cannot enter the Automatic Tuning mode when making any tuned RF level measurements.
Instrument Preset

FUNCTIONS
Includes all Power-Up and Default Conditions and HP-IB Clear

DESCRIPTION
When first turned on (during power-up), the Modulation Analyzer passes through a sequence of internal checks before it is ready to make measurements. The results of these checks are indicated internally as a service aid. (Refer to Section 8.) The running of the power-up sequence is indicated to the user by lighting all front-panel indicators (burned-out LEDs are evident at this time). After approximately 10 seconds, this sequence is completed.

When the Instrument Preset key is pressed, the instrument configures itself the same as during power-up, but bypasses the internal checks.

The Modulation Analyzer contains a battery back-up to its internal memory, which makes part of the memory non-volatile after the power has been switched off (powered-down)–even if the power cord is unplugged.

Information retained after power-down:

- The 8 instrument states stored in the Store/Recall registers.
- For RF Power:
  a. One set of zero and calibration (SAVE CAL) data.
  b. One table of 16 frequency/calibration factor pairs and the reference calibration factor used with RF power sensors.
  c. One table of 22 frequency/calibration factor pairs and the reference calibration factor used with microwave power sensors in the Frequency Offset mode.
  d. The state of Special Function 32.0 or 32.1 (dB and frequency resolution).
- For AM and FM:
  An AM calibration factor and an FM calibration factor (both in disabled mode).
Default conditions after power-up or instrument preset:

If no signal is present at the INPUT connector and no HP-IB controller is connected, the measurement conditions and front-panel annunciators are as follows:

**Measurement Conditions**

- **Tuning**: Automatic Signal Search
- **Measurement Mode**: Frequency
- **Modulation Output/Audio Input**: Blanked
- **Calibration Mode**: Off
- **HP-IB**: (See “COMMENTS”)
- **Special Functions**: (See below.)

If a suitable signal is present at the INPUT connector and no HP-IB controller is connected, the measurement conditions, front-panel annunciators, and Special Functions are as follows:

**Measurement Conditions**

- **Tuning**: Automatic, Low-Noise
- **Measurement Mode**: Frequency
- **IF Frequency**: Automatic Selection
- **Modulation Output/Audio Input**: Output FM
- **High-Pass Filter**: All Off
- **Low-Pass Filter**: All Off (15 kHz if input <10 MHz)
- **Calibration Mode**: Off
- **HP-IB**: (See “COMMENTS”)
- **Special Functions**: (See below.)

**Special Functions**

- **1-10**: suffix is set to 0
- **11 Previous Ratio**: off
- **Ratio Reference**: 100%
- **14 Limit**: off
- **Upper Limit**: 1300
- **Lower Limit**: 0.150
- **Upper/Lower Limit Code**: 0.005 (FREQ)
- **16 AM Calibration Factors**: 100% or previous power-down value
- **17 FM Calibration Factors**: 100% or previous power-down value
- **22 Service Request**: suffix set to 2;
- **Status Byte**: cleared
- **25 External Attenuation**: 0 dB
- **27 Frequency Offset Control**: 0 MHz
- **37 Calibration Factors, RF Power**: [both calibration factor tables from previous power-down]
PROCEDURE

To cause the instrument to run through its internal checks and reset the instrument to its default state, turn the instrument off, then on again.

To reset the Modulation Analyzer to its default state but bypass the internal power-up checks, select INSTR PRESET (Blue Key, AUTOMATIC OPERATION), or issue a device clear command from an HP-IB controller.

To initiate the internal power-up checks, select 40.0 SPCL.

HP-IB PROGRAM CODES

INSTR PRESET (Device Clear) = IP
SPCL = SP

The instrument can also be preset using the device clear bus command. (Refer to the Remote section on page 3–24.)

COMMENTS

Setting the Instrument to a Known State

The Instrument Preset feature is a very simple means of setting the instrument to a known state when writing test procedures involving the Modulation Analyzer.

Losing Instrument States with a New Controller Assembly

After plugging in a new controller Assembly, some or all of the instrument states stored through power-down may be non-existent. If this information is lost:

a. The Recall function reverts to the Instrument Preset state.

b. The RF Power measurement will: (1) display Error 15, (2) light the UNCAL and RECAL annunciators, and (3) use the default zero and calibration factors. (The RF power calibration factors must be re-entered.)

c. AM and FM calibration factors will be 100% when enabled (using Special Function 16 or 17).

Instrument Preset Clears Pending Require Service Messages

When the instrument is preset, any pending Require Service Message is cleared. (For more details, refer to Receiving the Clear Message, in Remote Operation.)

CLEAR Key

The HP-IB Clear message should not be confused with the front-panel CLEAR key or its CL HP-IB code. The HP-IB Clear message presets the instrument. The CLEAR key clears the display and returns the instrument to its previous state.

Alternative to Turning the Instrument Off and then On

Use special function 40.0 to cause the Modulation Analyzer to pass through its internal checks. (Special function 40.0 is not accessible from the HP-IB.)
Range Hold

FUNCTIONS
RANGE HOLD

DESCRIPTION
The Range Hold function freezes the current ranges being used by the Modulation Analyzer. This function, the converse of Automatic Operation, disables automatic tuning and sets Special Functions prefixed 1, 2, 3, 7, 9, and 10 to the current range settings. The following functions are not affected by Range Hold: High-pass and Low-pass Filters, FM De-emphasis, Measurement Detectors, and Display. Special Functions prefixed 1 through 10 that are already manually set are unaffected. The table below summarizes the effect of the Range Hold feature:

<table>
<thead>
<tr>
<th>Special Function Prefix</th>
<th>Measurement Function</th>
<th>Effect of RANGE HOLD on Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>RF Input Attenuation</td>

</tr>
<tr>
<td>AUTO TUNING</td>
<td></td>
<td>Selects Manual Tuning</td>
</tr>
</tbody>
</table>

PROCEDURE
To hold instrument settings in a specific measurement state, set the Modulation Analyzer as desired, then select RANGE HOLD.

To exit the Range Hold mode, select RANGE HOLD a second time or select AUTOMATIC OPERATION.

HP-IB PROGRAM CODE
Automatic Ranging = G0
RANGE HOLD = G1

Range Hold 3-213
COMMENTS

Altering Held Functions

Once settings are held with the Range Hold function, they can be altered by manually entering the desired setting. For example, the Range Hold function places the instrument in the manual tune mode; select AUTO TUNING (Blue Key, TRACK MODE) to re-enter the automatic tuning mode. Similarly, Special Functions can be used to set other functions or selectively return them to automatic operation.
FUNCTIONS

RATIO, PREVIOUS RATIO, LOG/LIN, Special Function 11 (Previous Ratio)

DESCRIPTION

The Ratio and Previous Ratio functions permit any measurement result to be scaled to a reference. The reference may be either a measurement result or a keyboard entry. Special Function 11.2 displays the current ratio reference.

The LOG/LIN key enables measurement results to be displayed in linear or logarithmic units, both absolute and relative. Examples of absolute units are kHz and mV (linear), or dBm (logarithmic). Examples of relative units are % and dB. For purposes of discussion, basic measurement units, such as % for AM or distortion, dB for SINAD, etc., (though actually relative units), are treated as absolute units. When the instrument displays % and dB as relative units (that is, when the ratio function is used), annunciator REL is added to the display.

All modulation and all frequency measurement results cannot be displayed with absolute, logarithmic units even though they can be displayed in relative, logarithmic units. (The LOG/LIN key is ignored.)

The Ratio function can be used with the following measurements:

- AM
- FM
- φM
- RF POWER
- FREQ
- AUDIO FREQ
- AUDIO DISTN
- IF LEVEL
- TUNED RF LEVEL
- FREQ ERROR
- SINAD (29.0 SPCL)
- Ext Audio RMS Level (30.0 SPCL)
- LO Frequency (33.0 SPCL)
- IF Frequency (34.0 SPCL)
- RF Level (35.0 SPCL)

The Ratio function is exited when:

- the RATIO key is pressed a second time,
- a new measurement is selected, or
- other measurement units are selected.

PROCEDURE

Select LOG/LIN anytime during a measurement to change the display between linear and logarithmic units, where permitted, for both absolute and relative (Ratio) displays.

To use the Ratio function:

1. Select the desired Measurement mode. Measurements possible with the ratio function are listed in “DESCRIPTION.”
2. Set the display to the desired reference value, either
   - adjust the signal parameter being measured for a display equal to the desired
     reference, or
   - enter the reference on the numeric keys. (If the reference value is to be negative, select
     minus; that is, the Blue Key, then the decimal key.)

3. Select RATIO. The display will show the measurement result relative to the reference.

To use the Previous Ratio function to restore a previously-entered ratio reference:

1. Select the desired Measurement mode.

2. Select PREVIOUS RATIO (Blue Key, RATIO). The display will show the measurement result
   relative to the original ratio reference. (The Modulation Analyzer uses the previous ratio reference
   regardless of what Measurement the instrument was in when the ratio reference was entered and
   regardless of the current Measurement mode.)

To display the ratio (or previous ratio) reference, key in 11.2 SPCL.

EXAMPLES

Assume 35.35 kHz FM deviation is displayed. Enter this value as the ratio reference for subsequent
measurements:

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>DISPLAY RATIO</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-IB (program codes)</td>
<td>R1 Display</td>
</tr>
</tbody>
</table>

The displayed measurement result is 100% REL if linear units are selected or 0 dB REL if logarithmic
units are selected. (The display will normally vary about these nominal values due to noise and the
typical one-count uncertainty in the measured result.)

If it is desired to scale FM measurement results relative to 50 kHz, set the Measurement mode to FM:

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>DISPLAY RATIO</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-IB (program codes)</td>
<td>50 R1 Display</td>
</tr>
</tbody>
</table>

If, as in the previous example, 35.35 kHz FM deviation was measured, the displayed measurement
result will be 70.7% REL if linear units are selected or −3.01 dB REL if logarithmic units are selected.
HP-IB PROGRAM CODES

LOG display = LG
LIN display = LN
PREVIOUS RATIO = R2
RATIO off = R0
RATIO on = R1
SPCL = SP

MEASUREMENT TECHNIQUE

In the Ratio mode, measurements are made in the same way as when not in the Ratio mode; however, before the result is displayed, the internal controller converts it to ratio. The following equations are used for computing ratio:

\[(M/R) \times 100\% = \% \text{ ratio for all measurements},\]
\[(20) \log_{10} (M/R) = \text{dB ratio for the following measurements}:^1 \text{ AM FM, } \Phi M, \text{ AUDIO DISTN, IF LEVEL, SINAD (29.0 SPCL), Ext Audio RMS Level, and (10) } \log_{10} (M/R) = \text{dB ratio for the following measurements}:^2 \text{ FREQ, AUDIO FREQ, FREQ ERROR, LO Frequency (33.0 SPCL), IF Frequency (34.0 SPCL),}\]

where M is the (undisplayed) measurement result and R is the ratio reference.

COMMENTS

Input/Output Status

The output signal at MODULATION OUTPUT/AUDIO INPUT is unaffected by the Ratio function.

Displaying the Reference

When using a currently-displayed measurement result as the ratio reference, that result actually becomes the reference. The only way to read this reference then is to display it via Special Function 11.2.

Display Flicker

Since displayed measurement results are computed from the actual physical measurements, least-significant digit flicker in the physical measurement can often lead to larger apparent flicker in the displayed result. For example, an AM measurement varying between 50.0% and 50.1% will vary between 100.0% and 100.2% REL with a ratio reference of 50 (or between 0.00 and 0.02 dB after switching to logarithmic units).

dB Ratio

When using dB ratio; any ratio reference or measurement result that causes ratio M/R (refer to previous equations) to equal 0, results in a display of Error 11 since the log of 0 is undefined.

---

1 When uV, mV, or V units are used, this equation provides the ratio result for RF POWER, TUNED RF LEVEL, and RF LEVEL (35.0 SPCL) measurements.

2 When watts units are used, this equation provides the ratio result for RF POWER, TUNED RF LEVEL, and RF LEVEL (35.0 SPCL) measurements.
Finer Resolution for dB Measurements

Special Function 32.1 enables a resolution of 0.001 dB. For audio frequency measurements, this special function enables a resolution of 0.1 Hz for frequencies from 100 to 250 kHz instead of the normally displayed resolution of 1 Hz. The selection of Special Function 32.0 or 32.1 is maintained through instrument power down.

32.0 Power is displayed with the normal measurement resolution of 0.01 dB.

32.1 Power is displayed with a measurement resolution of 0.001 dB.

32.2 Displays 0 if the normal measurement resolution is enabled (32.0 SPCL) and displays 1 if a finer resolution is enabled (32.1).

Modulation Flatness

When used in conjunction with track mode tuning, the Ratio function makes checking modulation flatness with respect to RF frequency very convenient. (Refer to RF Frequency Tuning on page 3–115 for a discussion of track mode tuning.)

Setting Measurement Limits

The ratio reference can also be entered as a limit reference. (Refer to Limit on page 3–219.)

Common Ratio Measurements

The following list provides some useful references for common ratio measurements:

- To display broadcast FM deviation relative to the common standard of 75 kHz, use 75 and linear units.
- To display FM in degrees, enter a value of 1.745 and select linear units.
- To display AM as dB down from the carrier, enter a value of 200 and select logarithmic units.
- To display rms calibrated average as true average, enter a value of 111.07 and select linear units.
- To display rms calibrated average as peak, enter a value of 70.7 and select linear units.

---

3 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
Limit

FUNCTIONS
RATIO, Special Function 14 (Limit)

DESCRIPTION
Using Special Function 14 and the RATIO key, lower and upper measurement limits can be entered into the Modulation Analyzer. Subsequent out-of-limit measurements will then cause the LIMIT annunciator to light.

When the Limit feature is enabled, the Modulation Analyzer can be configured to issue an HP-IB service request upon reaching a lower or upper limit (Refer to the Remote section in this manual on page 3-26.) The LIMIT light turns off five measurement cycles after the condition causing limiting is cleared.

Only one lower and one upper limit can be set. Once a limit has been set, it can be used only for that Measurement mode. (However, one limit can be used for one Measurement mode, and the other limit for another Measurement mode.) If, after setting limits, another Measurement mode is selected, the Limit feature is deactivated, but it is restored automatically when the former Measurement mode is re-entered.

Both limit references can be displayed, cleared, and restored; the status of the Limit function can be displayed; and the Measurement modes for which the limits were set can be displayed.

PROCEDURE
To establish a ratio reference and set it as a limit:

First enter the desired limit reference as a ratio reference and then set the lower or upper limit to that ratio reference:

1. Select the Measurement mode for which the limit is to be used.

2. Key in the reference value followed by the RATIO key (Do not use a terminator. The units will stay as currently displayed.) To change the sign of the reference, use the minus (−) key (Blue Key and the decimal point key.)

To set the limits:

3. Set the lower limit (14.1 SPCL) or the upper limit (14.2 SPCL) to the ratio reference.

4. To display the measurement result in absolute units, select RATIO again.
The Special Function codes pertaining to the Limit function are listed in the following table:

<table>
<thead>
<tr>
<th>Action</th>
<th>Special Function Code</th>
<th>Program Code HP-IB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clear limits; turn off LIMIT annunciator.</td>
<td>14.0 SPCL</td>
<td>14.0SP</td>
</tr>
<tr>
<td>set lower limit to RATIO reference.</td>
<td>14.1 SPCL</td>
<td>14.1SP</td>
</tr>
<tr>
<td>Set upper limit to RATIO reference.</td>
<td>14.2 SPCL</td>
<td>14.1SP</td>
</tr>
<tr>
<td>Restore lower limit.</td>
<td>14.3 SPCL</td>
<td>14.3SP</td>
</tr>
<tr>
<td>Restore upper limit.</td>

<tr>
<td>0.010</td>
<td>IF FREQUENCY (34.0 SPCL)</td>
<td>6.011</td>
<td>EXT AUDIO RMS LEVEL (30.0 SPCL)</td>
</tr>
</tbody>
</table>

**EXAMPLE**

To set an upper limit of 75 kHz FM deviation:

Read the FM deviation in kHz with an upper limit set at 75 kHz.
HP-IB PROGRAM CODES

The codes for performing the various limit operations are provided in “Procedures”.

RATIO off = R0
RATIO on = R1

COMMENTS

Relative Limits Not Possible

The test for out-of-limit results is performed on the actual measurement results, not upon the displayed number. Thus, if the Ratio feature is enabled simultaneously with the Limit feature, the limit test is still based on the measurement result, not the computed ratio. Limits cannot be set in terms of relative measurement results.

Importance of Key Sequence

If Special Function 14.1 or 14.2 is initiated with no previous numeric value, the ratio reference becomes the entered value. The desired limit must be entered before the Special Function numeric code.
Store/Recall

FUNCTIONS
STORE, RECALL

DESCRIPTION
The Modulation Analyzer can store a complete instrument state (including all front-panel functions and most Special Functions) in any of its eight storage registers. The stored data is retained in non-volatile memory when the instrument is off even when the power cord is removed. Any of these stored states can then be re-initiated.

PROCEDURE
To store the current instrument state, select STORE (Blue Key, 7). Then key in a register number (1 through 8).

To recall a previously-stored instrument state, select RECALL (Blue Key, 8). Then key in the desired register number (1 through 8).

HP-IB PROGRAM CODES
RECALL = RC
STORE = TR

COMMENTS
Regarding storage of RF power calibration factors:
- The current reference calibration factor and the frequency/calibration-factor pair can be stored.
- Manual calibration factors can be stored.
- The table of calibration factors cannot be stored with this function, but two tables of calibration factors can be separately stored in the instrument’s non-volatile memory. (Refer to RF Power under “Comments” on page 3–79.)
Frequency Offset Control

FUNCTIONS
Special Function 27 (Frequency Offset Control)

DESCRIPTION
Using an external mixer and local oscillator (LO) to down-convert the input signal, the frequency range of the Modulation Analyzer can be extended into the microwave region. The Frequency Offset mode allows the Modulation Analyzer to keep track of the frequencies involved in the down-conversion so the user can be freed from this task. This feature operates for frequencies up to 42 GHz.

The full complement of instrument measurements can be made on the down-converted microwave signal (with the same signal restrictions that apply in the normal frequency range). For best measurement accuracy, the external LO should be a source free from microphonic, residual FM, and drift since these signal impurities translate directly on to the down-converted signal. Use of a synthesized signal source is recommended. Examples of suitable signal sources are the HP 8340A, 8672A, and 8673A.

The RF Power measurement mode uses a separate table of frequencies and calibration factors in the Frequency Offset mode. Frequency entries can range from 0 to 110 GHz. (Refer to RF Power on page 3–71 for a procedure for entering calibration factors.)

A rear-panel FREQ OFST TTL OUT connector can indicate to external circuits whether the Modulation Analyzer is in the Frequency Offset mode and whether the LO is above or below 18 GHz. Use this feature to control external RF switches to route or bypass the input signal between external mixers.

Use Special Function 27 to enter and exit the Frequency Offset mode and to enter and display the LO frequency.

PROCEDURE
To down-convert a microwave input signal into the range of the Modulation Analyzer, set an external microwave signal source to a level suitable as an LO for the external mixer. Set the frequency of the external LO source to within 1300 MHz of the microwave input signal. Connect the external LO source to the L port of the external mixer. Connect the microwave input signal to the appropriate input port of the external mixer. Connect the output port of the mixer to the RF INPUT connector or to the input of a sensor module connected to the Modulation Analyzer.

Key in 27.3 SPCL, then select the LO frequency (in MHz) and select MHz to enter the Frequency Offset mode.
The following table summarizes the various Frequency Offset Control special functions:

<table>
<thead>
<tr>
<th>Action Regarding Frequency Offset Control</th>
<th>Special Function Code</th>
<th>Program Code HP-IB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exit Frequency Offset Mode</td>
<td>27.0 SPCL</td>
<td>27.0SP</td>
</tr>
<tr>
<td>Re-enter Frequency Offset Mode</td>
<td>27.1 SPCL</td>
<td>27.1SP</td>
</tr>
<tr>
<td>Display the External LO Frequency</td>
<td>27.2 SPCL</td>
<td>27.2SP</td>
</tr>
<tr>
<td>Enter and Enable the LO Frequency*</td>
<td>27.3 SPCL</td>
<td>27.3SP</td>
</tr>
</tbody>
</table>

*After Special Function 27.3 is entered, enter the frequency of the LO (in MHz) Frequencies from 0 to 40700 MHz can be entered.

Having entered the appropriate LO frequency, either manually tune to the microwave input frequency by pressing the appropriate numeric keys followed by the MHz key or let the Modulation Analyzer automatically tune to the input signal.

Perform instrument measurements as usual. Select DISPLAY FREQ (Blue Key, kHz ↑) to display the microwave input frequency.

**HP-IB PROGRAM CODES**

All HP-IB codes for manipulating the frequency offset control using Special Function 27 are provided in “Procedures”.

DISPLAY FREQ = FR  
MHz = MZ

**MEASUREMENT TECHNIQUE**

The external LO mixes with the microwave input signal to create a difference frequency which is the input to the Modulation Analyzer. The frequency of the microwave input signal must be within 1300 MHz of the external LO to be within the measurement range of the Modulation Analyzer. The LO frequency is manually entered by the operator using Special Function 27.3. The Modulation Analyzer, thereafter, uses that LO frequency to compute the microwave input signal frequency regardless of the actual frequency of the LO.

If tuning is in the automatic mode, the Modulation Analyzer computes and displays the microwave input frequency as:

(frequency of LO) – (frequency at INPUT).

If tuning is manual, the Modulation Analyzer computes and displays the microwave input frequency as:

(frequency of LO) ± (frequency of INPUT).

The difference is computed when the manually-entered frequency is less than the LO frequency. The sum is computed when the frequency is greater. The sense (+ or –) of the math operation remains the same regardless of the actual microwave input frequency, even if automatic tuning is selected.

The displayed frequency is always based on the frequency actually at the Modulation Analyzer’s input and not the manually-entered input frequency, which serves only to set the Modulation Analyzer’s internal LO. Manually entering a new microwave input frequency, entering a new LO frequency, or initiating automatic tune always retunes the Modulation Analyzer.

When the manually entered LO frequency is displayed (Special Function 27.2), a minus (–) sign preceding the frequency indicates that the math operation is a sum.
COMMENTS

Range Limitations

If the entered LO frequency and microwave input frequency differ by more than 1300 MHz (or less than 0.15 MHz), an out-of-range error is displayed (Error 10). (Even though the Modulation Analyzer appears to measure signals over the range 0 to 110 GHz, the instrument itself can tune to and measure signals only over the range of 0.15 to 1300 MHz. An exception to this is the RF Power measurement.)

Default Condition

At power-up, the math operation (described under “MEASUREMENT TECHNIQUE”) is a difference.

Peak+ and Peak– Functions Reversed

When FM or ΦM measurements are made, the Peak+ and Peak– functions are reversed whenever the external LO frequency is less than the microwave input frequency.

HP-IB: Service Request Mask

Using Special Function 22 (bit weight 16), the Modulation Analyzer can be unmasked to output a Service Request whenever the Frequency Offset mode changes state (that is, entered or exited) or when the instrument is manually retuned. (Refer to the Remote section on page 3-26.)

FREQ OFFSET TTL OUT

When the Modulation Analyzer is in the Frequency Offset mode, the rear-panel FREQ OFFSET TTL OUT connector outputs a voltage which is dependent upon the state of the Frequency Offset mode and the entered external LO frequency. The state of the output is shown in the following table:

<table>
<thead>
<tr>
<th>State of Frequency Offset Mode</th>
<th>Entered LO Frequency (GHz)</th>
<th>Nominal Voltage at FREQ OFFSET TTL OUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Any</td>
<td>0</td>
</tr>
<tr>
<td>In</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>In</td>
<td>&gt;0 but ≤ 18</td>
<td>+5</td>
</tr>
<tr>
<td>In</td>
<td>&gt;18 but ≤ 40.7</td>
<td>+3</td>
</tr>
</tbody>
</table>
FILTERS, RF and IF

FUNCTIONS
Special Function 3 (RF and IF Filters)

DESCRIPTION

RF Filter
To eliminate unwanted low-frequency signals in the RF signal path, an RF filter can be inserted. Special Function 3 manually selects the 5.25 MHz High-Pass Filter. Since the IF generally responds to signals below 2.5 MHz, the filter eliminates any low frequencies that might be present on the input. (For input signals between 150 kHz to 10 MHz, the filter should be switched out.)

IF Filters
The Modulation Analyzer down-converts (heterodynes) the RF input to the IF. The IF is usually centered at 1.5 MHz for input signals 10 to 1300 MHz. (An IF of 455 kHz can be manually selected.) For signals between 2.5 MHz and 10 MHz, the IF is 455 kHz. Below 2.5 MHz, the signal is passed directly into the IF without down-conversion (unless the 455 kHz IF has been manually selected). IF filters determine the frequency response of each IF.

When the 1.5 MHz IF is selected, the IF frequency response is determined by the 2.5 MHz Low-Pass (LP) Filter.

When the 455 kHz IF is selected, the 455 kHz Bandpass (BP) Filter determines the IF frequency response.

Various combinations of these filters can be manually inserted using Special Function 3. (Special Function 3 will override automatic filter selection for Tuned RF level measurements.)

PROCEDURE
To select a desired combination of RF and IF filters, or to re-enter the automatic selection mode, key in the corresponding Special Function code, then press the SPCL key:

<table>
<thead>
<tr>
<th>Special Function Code</th>
<th>Program Code HP-IB</th>

Filters, RF and IF 3-229
HP-IB PROGRAM CODES

The HP-IB codes for selecting various combinations of RF and IF filters are provided in "PROCEDURE".

BLOCK DIAGRAM

![Block Diagram of RF and IF Filters]

COMMENTS

Default Condition
When the instrument is first powered up or when Automatic Operation or Instrument Preset is selected, RF and IF Filters are placed in the automatic selection mode.

Automatic Retuning
When a new IF is selected, the instrument immediately retunes.

Increased Sensitivity and Selectivity
Many measurements can typically be made on very low-level signals. Using the narrow bandwidth of the 455 kHz IF for signal frequencies less than 2.5 MHz (but in the manual down-convert mode) or greater than 10 MHz increases the sensitivity and selectivity of the Modulation Analyzer. (There are, however, restrictions on modulation, and measurement accuracy may decrease.) Manual deletion of RF input attenuation also increases sensitivity. (Refer to RF Input Attenuation on page 3-231.)
RF Input Attenuation

FUNCTIONS
Special Function 1 (RF Input Attenuation)

DESCRIPTION
The RF input attenuation and is usually automatically selected but can be manually set by keyboard entry using Special Function 1.

PROCEDURE
To set the input attenuation to a selected range, or to enter an automatic selection mode, key in the corresponding special function code, then select SPCL:

<table>
<thead>
<tr>
<th>RF Input Attenuation</th>
<th>Special Function Code</th>
<th>Program Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic Selection</td>
<td>1.0 SPCL</td>
<td>1.0SP</td>

<td>1.5 SPCL</td>
<td>1.5SP</td>
</tr>
<tr>
<td>50 dB</td>
<td>1.6 SPCL</td>
<td>1.6SP</td>
</tr>
</tbody>
</table>

COMMENTS

Default Condition
When the Modulation Analyzer is first powered up, or when Automatic Operation or Instrument Preset is selected, the RF input attenuation is placed in the automatic selection mode (Special Function 1.0).

Error 02, 03
If the RF input attenuation is manually set to a range that causes the input signal level to overdrive the input mixer, Error 02 is displayed. If the RF input attenuation is manually set so the signal level reaching the IF circuits is too low for accurate measurements, Error 03 is displayed.
Manual Settings Not Allowed with RF Level Measurements

Manual setting of RF input attenuation is overridden when RF Level measurements are selected.

Block Diagram of RF Input Attenuation
Error Message Disable Control

FUNCTIONS
DISABLE ERROR, Special Function 8 (Error Message Disable and Enable)

DESCRIPTION
Error Messages are one means the Modulation Analyzer uses to safeguard measurement integrity. When the instrument senses a potential error-causing situation, an Error Message code is displayed to alert the user of the condition. The Error Message code indexes an Error Message, which describes the current errors. (Refer to Error Message Summary on page 3-247.)

When the Modulation Analyzer is in its Automatic Operation mode, Error Messages are selectively enabled, depending on the measurement being made, to assure the broadest range of calibrated measurements. Some Error Messages, however, can be selectively disabled or enabled using Special Function 8. Disable Error performs the same function as Special Function 8.7 (Errors 01, 02, 03, and 04 disabled).

Most combinations of Errors 01 through 04 can be disabled or enabled by the operator to customize the behavior of the instrument to meet a particular set of measurement requirements. Special Function 8.8 (Errors 01 through 04 enabled) sets up the Modulation Analyzer as a calibrated receiver. (Refer to "COMMENTS" for further elaboration.)

The following table lists the Error Messages conveyed by Errors 01 through 04:

<table>
<thead>
<tr>
<th>Error</th>
<th>Error Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>Signal out of IF range</td>

Error Message Disable Control 3-233
PROCEDURES

To disable Errors 01, 02, 03, and 04, select DISABLE ERROR (Blue Key, RANGE HOLD). This key selection enables 8.7 SPCL.

To selectively enable or disable combinations of Errors 01 through 04, enter the Special Function code that corresponds to the condition desired, then select SPCL. The codes for the various conditions are listed in the following table:

<table>
<thead>
<tr>
<th>Error Condition</th>
<th>Special Function Code</th>
<th>Program Code HP-IB</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

HP-IB PROGRAM CODES

The HP-IB program codes for selectively disabling combinations of Errors 01 through 04 are provided in "PROCEDURE".

DISABLE ERROR = B1
Clear DISABLE ERROR function = B0

COMMENTS

Input/Output Status

When Error Messages are disabled, the accuracy of the displayed measurement and the fidelity of the signal at the output of the MODULATION OUTPUT/AUDIO INPUT are not safeguarded. When all the errors are enabled, displayed results are calibrated and the output of MODULATION OUTPUT/AUDIO INPUT is entirely safeguarded.

Disable Error 04 Inhibits Audio Autoranging

When Error 04 is disabled, the Modulation Analyzer automatically ranges to a less sensitive range when the signal level requires, but it does not range back when the audio level is reduced. Thus, if a transitory peak audio signal is detected, the Modulation Analyzer will up-range the audio range to accommodate the peak but will not down-range after it has passed. Audio autoranging is then prevented from interfering with other measurements such as input frequency. (Refer to Audio Range on page 3-183.)

Special Function 8 Overrides Automatic Selection

Note that Special Functions 8.1 through 8.8 override the automatic selection for all measurement modes. Thus, error messages that may be appropriately disabled for one measurement mode (such as frequency) may be inappropriate for another measurement mode (such as AM).
Limits to Disabling Error Messages

Disabling some error messages (such as Error 04) often give rise to other error messages that cannot be disabled (such as Error 07).

Safeguarding the Signal Fidelity at the Modulation Output

Special Function 8.8 is sometimes referred to as the “calibrated receiver” mode of operation. It assures that the output from MODULATION OUTPUT/AUDIO INPUT is safeguarded for most measurements. Some tuned, non-modulation measurement modes (such as frequency) do not completely safeguard the signal fidelity at this output since accurate demodulation is not the primary goal of that measurement mode.

Identify Currently Disabled Error Messages

Use the Special Display and the Special Special Display to identify currently disabled error messages. (Refer to Special Functions on page 3-238.)
Special Functions

FUNCTIONS
All Special Functions prefixed 1 to 39

DESCRIPTION

General Information
Special functions enable extended use of the instrument beyond the control normally available from dedicated front-panel keys. The special functions are best used after a thorough understanding of the instrument is grasped.

Special functions are accessed via keyboard entry of the appropriate numeric code terminated by the SPCL key. (Refer to "Procedures"). The codes comprise a prefix, decimal, and suffix. Special functions are disabled in different ways, depending on the function. Refer to the following comprehensive table for actions which clear or disable any special function. Special functions are grouped by their prefixes into three categories as follows:

Prefix 0
Prefix 0 is the Direct Control Special Function intended for use in servicing the Modulation Analyzer (discussed in detail in Section 8). All instrument error messages and safeguards are inactive. If the Direct Control Special Function is entered inadvertently, press AUTOMATIC OPERATION.

Prefixes 1 to 39
Prefixes 1 to 39 are the User Special Functions that are used during normal instrument operation when a special configuration, a special measurement, or special information is required. All error messages and most safeguards remain in effect unless the operator disables them. These special functions are described in the table in this instruction.

Prefixes 40 to 99
Prefixes 40 to 99 are the Service Special Functions used to assist in troubleshooting an instrument fault (discussed in detail in Section 8). The functions available include special internal measurements, software control, and special service tests and configurations. Most instrument safeguards are relinquished. If a Service Special Function is entered inadvertently, press AUTOMATIC OPERATION. Repair personnel can gain arbitrary control of the instrument as an aid in troubleshooting.

Viewing Special Function States
In addition to completing the entry of special function codes, the SPCL key enables viewing of some special function settings. The operator-requested settings of Special Functions prefixed 1 through 10 can be viewed by pressing the SPCL key once (following no numeric entry). This display is called the Special Display. If some of these Special Functions are in automatic modes (generally the 0-suffix setting), the actual instrument settings of these functions can be displayed by pressing the SPCL key a second time while the Special Display is still active. This display is called the Special Special Display. Both displays can be disabled by pressing any key except the Blue Key, LOCAL, or S (shift) key. (While either display is active, pressing the SPCL key selects the other display.)

A summary of User Special Functions is provided at the end of this instruction. Also included in this instruction are procedures for initiating special functions and for obtaining the Special Display and the Special Special Display.
PROCEDURES

Entering Special Functions
To use a special function, key in the corresponding code, then select SPCL.

Special Display
To display the user-requested modes of special functions prefixed 1 through 10, select SPCL alone one time. The digit position (noted beneath the display) corresponds to the special function prefix, and the number displayed in that position corresponds to the special function suffix.

Special Special Display
To determine the actual instrument settings corresponding to special functions prefixed 1 through 10, press the SPCL key alone once while the Special Display is active. (If the Special Display is not active, press the SPCL key twice to get this display.) The digit position corresponds to the special function prefix, and the number displayed in that digit corresponds to the special function suffix.

HP-IB PROGRAM CODES
All special function codes are formed by the special function number followed by the code “SP”. For example, the code for Special Function 7.3 is “7.3SP”.

For special function codes with zero as a suffix, force a single space if the zero is to be omitted. For example, “10.0SP” could be “10. SP”

EXAMPLES

Entering Special Functions
To display the frequency of the signal in the IF (Special Function 34):

<table>
<thead>
<tr>
<th>LOCAL (keystrokes)</th>
<th>CODE</th>
<th>FUNCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 4 0 SP</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HP-IB (program codes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code 34.0 SP</td>
</tr>
<tr>
<td>Function</td>
</tr>
</tbody>
</table>
Viewing the Special Display

When SPCL is pressed alone once, the following display might result:

```
0100012000
```

Special Special Display

When SPCL is pressed again, the following display might result: (The user-selected Special Functions shown in the previous example are repeated in the Special Special Display. The Special Functions that were left in the automatic selection mode will display the suffix that was automatically selected.)

COMMENTS

Omit Zero Suffixes

If a special function has a suffix of zero, the zero need not be entered. For example, 10.0 SPCL equals 10.SPCL. (However, 22.2 SPCL does not equal 22.20 SPCL nor does 18.1 SPCL equal 18.10 SPCL.) If entering a special function code evokes Error 21 (invalid key sequence), the special function requested has not been executed.

HP-IB

Force a single space in “10. SP” if the zero is to be omitted.

CLEAR Key

If an error is made while keying in the special function code, select CLEAR and re-enter the code.
DETAILED DESCRIPTIONS OF ALL SPECIAL FUNCTIONS

1. RF Input Attenuation.  Use this special function to select RF input attenuation to eliminate input overload or to improve measurement sensitivity. For more details about this function, refer to RF Input Attenuation on page 3-231.

1.0 Automatic selection
1.1 Attenuation of 0 dB
1.2 Attenuation of 10 dB
1.3 Attenuation of 20 dB
1.4 Attenuation of 30 dB
1.5 Attenuation of 40 dB
1.6 Attenuation of 50 dB

2. Audio Range Selection.  Use this special function to set the display resolution for modulation measurements. The Modulation Analyzer's display resolution is dependent on the modulation being measured and the detector being used. For example, in FM measurements, Special Function 2.4 can only display 0.01 Hz resolution when the deviation being measured is less than 0.04 peak kHz and when the RMS detector is selected. Because the special function is so complex, it is not described in detail here. Refer to Audio Range on page 3-183, for detailed tables for this function.

3. RF and IF Filters.  Use this special function to change the Modulation Analyzer's RF and IF filters. (Refer to Filters, RF and IF on page 3-229 for information about the usefulness of changing these filters.)

5. Audio Detector Response.  Use this special function to help stabilize measurements on unstable or noisy signals when making modulation or SINAD measurements.  

5.0 Fast response time.
5.1 Slow response time.

---

1 The slow response time for SINAD is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
6. Automatic Level Control. Use this special function to speed up the ALC response time or to disable the ALC. (The faster ALC response time degrades AM accuracy at rates less than 1 kHz.) Disabling the ALC, in conjunction with the rear-panel AM Output connector, can be used to measure AM at very low modulation rates. Disabling the ALC also permits measurement of absolute changes in AM depth without regard to changes in carrier level.

6.0 Slow ALC (for AM rates greater than 20 Hz).
6.1 Fast ALC (for AM rates greater than 1 kHz).
6.2 ALC off.

7. RF Frequency Resolution. Use this special function to manually set the display resolution during frequency measurements (including RF, IF, and LO frequencies). Note that with finer resolution, measurement time increases.

7.0 Automatic selection.
7.1 Resolution of 10 Hz.
7.2 Resolution of 100 Hz. (When using an external LO value greater than 20 GHz, 7.1 SPCL selects 100 Hz resolution.)
7.3 Resolution of 1 kHz.
7.4 Resolution of 0.1 Hz for input signals less than 10.1 MHz; resolution of 1 Hz for signals from 10.1 MHz through 1300 MHz. (When measuring frequencies as high as 1300 MHz, measurement time with this resolution is approximately 20 seconds.)

8. Error Message Disable Control. Most combinations of Errors 01 through 04 can be disabled or enabled to customize the behaviour of the instrument to meet a particular set of measurement requirements. When the Modulation Analyzer uses automatic selection of error messages, these messages are selectively enabled, depending on the measurement being made, to assure the broadest range of calibrated measurements. Error Message Disable Control on page 3-233 has a table that lists the errors that are automatically disabled during each measurement.

8.0 Automatic selection of disabled error messages.
8.1 Disables Error 01.
8.2 Disables Errors 02 and 03.
8.3 Disables Errors 01, 02, and 03.
8.4 Disables Error 04.
8.5 Disables Errors 01 and 04.
8.6 Disables Errors 02, 03, and 04.
8.7 Disables Errors 01, 02, 03, and 04. Performs the same function as DISABLE ERROR (Blue Key, RANGE HOLD).
8.8 Enables Errors 01, 02, 03, and 04. This ensures that the output from MODULATION OUTPUT is safeguarded for most measurements. Some tuned, non-modulation measurement modes (such as frequency) do not completely safeguard the signal fidelity at this output since accurate demodulation is not the primary goal of that measurement mode.

---
2 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.
10. **RF Power Range.** Use this special function to manually select one of the five internal power ranges. In most applications, the Modulation Analyzer will automatically select the appropriate power range. The following table lists the power ranges and their associated special function codes.

10.0 Automatic selection.
10.1 Range #1 (most sensitive range).
10.2 Range #2.
10.3 Range #3.
10.4 Range #4.
10.5 Range #5 (least sensitive range).

11.2. **Previous Ratio.** Use this special function to display the reference set with the RATIO key.

12. **FM Calibration for Another Instrument in the HP 8902 and HP 8902 RF Signal Analyzer Family.** Use this special function to compute an FM calibration factor for another RF signal analyzer that has no internal calibrator, or that has an internal calibrator that is to be cross checked. (For a complete procedure for FM calibration, refer to *FM Calibration* on page 3-155.)

12.0 Display the computed peak FM.
12.1 Display the demodulated peak residual FM.
12.2 Display the demodulated peak FM.

13. **AM Calibration for Another Instrument in the HP 8902 and HP 8902 RF Signal Analyzer Family.** Use this special function to compute an AM calibration factor for another RF signal analyzer that has no internal calibrator, or that has an internal calibrator that is to be cross checked. (For a complete procedure for AM calibration, refer to *AM Calibration* on page 3-141.)

13.0 Display the computed peak AM.
13.1 Display the demodulated peak residual AM.
13.2 Display the demodulated peak AM.

14. **Measurement Limits.** Use this special function in conjunction with the RATIO key to set lower and upper measurement limits. (For a complete procedure on setting measurement limits, refer to *Limit* on page 3-219.)

14.0 Clear limits; turn off LIMIT annunciator.
14.1 Set a lower limit to the Ratio reference.
14.2 Set an upper limit to the Ratio reference.
14.3 Restore the lower limit.
14.4 Restore the upper limit.
14.5 Display the lower limit.
14.6 Display the upper limit.
14.7 Display the code for the measurement the lower limit applies to.
14.8 Display the code for the measurement the upper limit applies to.
14.9 Display the limit status in the format “Lower,Upper” where 0=disabled and 1=enabled.
15. **Time Base Check.** Use this special function to check the status of the time base being used by the Modulation Analyzer. (More information about the time base is on page 3-3.)

15.0 Display whether the internal, Option 002 time base oven is warm enough to create a stable source; 0 = warm. Error 12 is displayed if the time base is cold.

15.1 Display whether the internal or external time base is being used; 0 = internal and 1 = external.

16. **AM Calibration Factor.** This special function enables you to disable, enable, or display the current AM calibration factor. Front-panel keys SAVE CAL (Blue Key, CALIBRATE) and % CAL FACTOR (Blue Key, MHz) can also be used to enable and display the calibration factor. (For a complete procedure for AM calibration, refer to AM Calibration on page 3-141.)

16.0 Disable the AM calibration factor.
16.1 Enable the AM calibration factor.
16.2 Display the AM calibration factor. (Displays 0 if not enabled.)

17. **FM Calibration Factor.** This special function enables you to disable, enable, or display the current FM calibration factor. Front-panel keys SAVE CAL (Blue Key, CALIBRATE) and % CAL FACTOR (Blue Key, MHz) can also be used to enable and display the calibration factor. (For a complete procedure for FM calibration, refer to FM Calibration on page 3-155.)

17.0 Disable the FM calibration factor.
17.1 Enable the FM calibration factor.
17.2 Display the FM calibration factor. (Displays 0 if not enabled.)

18. **NN Tone Burst Receiver.** Use this special function to measure the frequency of squelch tones. A time delay of NN ns is inserted between detection of a carrier and unsquelching of the output at the MODULATION OUTPUT connector. The range of NN is 1 to 99 ms. If NN is 0, the delay is 99 ms. (Refer to Tone Burst Receiver on page 3-165 for more information about this function.)

21. **HP-IB Address.** Use this special function to display the HP-IB address in the form: AAAAAA.TLS, where:
AAAAAAA is the address in binary,
T = 1 = talk only,
L = 1 = listen only, and
S = 1 = requesting service.

22. **Service Request.** Use this special function to set up a service request mask. A value of NN from 0 to 63 sums the weighted conditions below to set up a service request mask. The summed, weighted conditions are displayed when NN is 64. Refer to page 3-29 for more information about this service request mask.

1 Data ready
2 HP-IB error (cannot be disabled)
4 Instrument error
8 Limit exceeded
16 Frequency Offset mode state change
32 RECAL or UNCAL
64 read back SRQ mask
23. **External LO (Option 030 Only).** Use this special function when making Selective Power Measurements using an external LO. (Refer to *Selective Power Measurements* on page 3-95 for more information about this measurement.)

23.0 Return the LO to internal.
23.1 Set the LO to external.
23.2 Display the status of the LO (0=Internal, 1=External).

24. **Selective Power Measurement (Option 030 Only).** Use this special function when measuring adjacent channel power or single-sideband noise. (Refer to *Selective Power Measurements* on page 3-95 for more information about this measurement.)

24.0 Sets the Modulation Analyzer to the Selective Power Measurement Mode.
24.1 Selects the wide-bandwidth IF filter for adjacent-channel or cellular radio power measurements; displays the IF level (in volts).
24.2 Establishes the level measured with 24.1 SPCL as the 0 dB reference.
24.3 Selects a narrower bandwidth IF filter than 24.1 SPCL for adjacent-channel power measurements; displays the IF level (in volts).
24.4 Establishes the level measured with 24.3 SPCL as the 0 dB reference.
24.5 Selects a very narrow bandwidth IF filter (2.5 kHz) for the single-sideband noise measurement; displays the IF level (in volts).
24.6 Establishes the level measured with 24.5 SPCL as the 0 dB reference.
24.7 Displays the noise measurement as normalized to a 1 Hz bandwidth.
24.8 Enables setting of the value of the noise measurement bandwidth.
24.9 Displays the value of the noise measurement bandwidth.

25. **Current Value of External Attenuation.** Use this special function in conjunction with dB EXT ATTEN (Blue Key, LOG/LIN) to scale level measurements to correctly indicate the power at the input of an external attenuator or amplifier connected to the Modulation Analyzer. (For information on setting the value of external attenuation, refer to *External Attenuation* on page 3-105.)

25.2 Display the current offset in dB. (Amplification is shown as a negative attenuation value.)

27. **Frequency Offset Control.** Use this special function when making measurements on down-converted input signals. (The Modulation Analyzer can measure frequencies to 42 GHz when an external mixer and LO are used to down-convert the input signal. Refer to *Frequency Offset Control* on page 3-225 for requirements of the local oscillator and mixer.) The Frequency Offset Control special function allows the Modulation Analyzer to keep track of the frequencies involved in the down-conversion.

27.0 Exit the Frequency Offset Mode.
27.1 Enter the Frequency Offset Mode.
27.2 Display the external LO frequency.
27.3 Prepare to enter and enable the LO frequency. After entering 27.3 SPCL, enter the frequency of the LO (in MHz). Frequencies from 0 to 40700 MHz can be entered.

29.0 **SINAD Measurement.** Use this special function to make SINAD (Signal to Noise And Distortion) measurements on either internally demodulated signals or externally applied audio signals.
30.0 External Audio RMS Level Measurement. Use this special function to measure the true rms level of an audio signal applied to the Modulation Analyzer’s AUDIO INPUT connector.

32. dB and Frequency Resolution. During RF Power measurements, and measurements that use the Ratio function, use this special function to display dB measurements with resolution in 0.001 dB instead of the normally displayed resolution of 0.01 dB. During audio measurements, use this special function to display 0.1 Hz resolution from 100 to 250 kHz. The selection of Special Function 32.0 or 32.1 is maintained through instrument power down (the Modulation Analyzer being turned off and then on).

32.0 Power is displayed with normal measurement resolution of 0.01 dB.
Audio frequency is displayed with the normal resolution of 1 Hz for frequencies from 100 to 250 kHz.

32.1 Power is displayed with measurement resolution better than 0.004 dB.
Audio frequency is displayed with a resolution of 0.1 Hz for frequencies from 100 to 250 kHz.

32.2 Displays 0 if the normal measurement resolution is enabled (32.0 SPCL) and displays 1 if a finer resolution is enabled (32.1 SPCL).

33.0 LO Frequency Measurement. Use this special function to display the LO frequency for the signal being measured.

34.0 IF Frequency Measurement. Use this special function to display the IF frequency for the signal being measured. Special Function 3 enables you to manually select the IF for frequencies above 10 MHz. (Refer to Filters, RF and IF on page 3-229.)

35.0 RF Level Measurement. Enables the Modulation Analyzer to measure the peak RF power. This measurement is selected when RF POWER is selected and no power sensor is connected to the SENSOR input.

37. RF Power Calibration Factors. Use this special function to manipulate RF Power calibration factors. An extensive table in RF Power on page 3-74 summarizes each of these special functions. Two tables are available with the same special function. The table being used is determined by the status of Frequency Offset Mode (Special Function 27).

37.0 Use automatic calibration factors.
37.1 Use manual calibration factors.
37.2 Display calibration factor status (0=automatic, 1=manual).
37.3 Enter calibration factor.
37.4 Display table size.
37.5 Prepare to recall the reference calibration factor.
37.6 Prepare to recall the next frequency/calibration factor pair.
37.9 Clear the table.

---

3 This special function is not available with firmware date codes 234.1985 and below. (To display the firmware date code, select 42.0 SPCL.) To order a ROM set that contains this special function, contact the nearest HP sales office.

3-246
Error Message Summary

DESCRIPTION

Error Messages are one means the Modulation Analyzer uses to safeguard measurement integrity. When the instrument senses a potential error-causing situation, an Error Message code is displayed to alert the user of the condition. The Error Message code indexes an Error Message which describes the current error. Error Messages indicate operating problems, incorrect keyboard entries, or service-related problems. The error message is usually cleared when the error condition is removed.

Two types of error message display formats are used:

Error NN: The numerical value (NN) of the error message is displayed and

- - No detectable signal falls within the IF passband. Either no signal is at the input, or the instrument cannot tune to find the applied signal. (For example, it might be manually tuned far enough away from an input signal that no power is detected in the IF.) This display is output to the HP-IB as Error 96 using the HP-IB output format described in “HP-IB Output Format”.

- - A signal has been detected but, for various reasons, a measurement result is not yet available. The instrument might be still completing the measurement requested, or in some cases, unable to complete a measurement because of manual settings of special functions. (For example, when frequency measurements are made on a low-level input signal with high AM depth, or when the RF input attenuation is improperly set.) This display is never output to the HP-IB and typically indicates a transitory state in instrument operation.

Error messages are grouped by error code as follows:

Errors 01 through 19 and 90 through 99

These messages are Operating Errors which indicate a condition has not been met to assure a calibrated measurement. Operating Errors can usually be cleared by readjustment of front-panel controls (usually, the easiest way is to select AUTOMATIC OPERATION). The DISABLE ERROR key or Special Function 8 can be used to selectively disable Errors 01 through 04. (Refer to Error Message Disable Control on page 3–233.)

Errors 20 through 29

These messages are Entry Errors which indicate an invalid key sequence or keyboard entry. These errors require that a new keyboard entry or function selection be made. Some of these error displays time out after a few seconds and then allow the display to return to the current measurement.

Errors 40 through 89

These messages are Service Errors generated to provide service-related information. They must be enabled to be displayed since they are not displayed in normal instrument operation. Service Error Messages are discussed in Section 8 of the Service Manual.
HP-IB

HP-IB Output Format

The HP-IB output format for errors is shown below:

```
+900000 DD 00 E+01 CR LF
```

For example, Error 02 is output to the HP-IB as +9000000200E+01CRLF. Once an error has been input to the computing controller, the error code is simply derived by subtracting $9 \times 10^{10}$ from the input number, then dividing the result by 1000.

Error Messages

The following table describes all Operating Errors and includes the error code, message, and the action typically required to remove the error-causing condition. The COMMENTS column that follows provides additional information and references pertaining to particular error messages.

COMMENTS

Error 01

With the 1.5 MHz IF, the IF frequency must be 1.5 MHz ±50 kHz.
With the 455 kHz IF, the IF frequency must be 455 kHz ±2.5 kHz (±5 kHz in Tuned RF level).
Refer to RF Frequency Tuning. Error 01 disables MODULATION OUTPUT/AUDIO INPUT.

Error 02

Refer to RF Input Attenuation and Gain for nominal input levels. Error 02 disables MODULATION OUTPUT/AUDIO INPUT.

Error 03

Refer to RF Input Attenuation and Gain for nominal input levels. Error 03 disables MODULATION OUTPUT/AUDIO INPUT.

Error 04

Error 04 designates either an improperly set audio range, or an attempt to measure modulation levels greater than those specified. Refer to Audio Range.

Error 05

Error 05 often occurs when FM or RM measurements are attempted on low-level signals with high AM depth (greater than 90%). Error 05 disables MODULATION OUTPUT/AUDIO INPUT.

Error 06

Maximum allowable input level is 7 Vrms (1W peak).

Error 07

If displayed during modulation measurements, increase audio range. If displayed during level measurements, increase RF input attenuation or increase RF power range.

Error 08

If the connection from CALIBRATION AM/FM OUTPUT to RF INPUT is intact, this error may indicate calibrator malfunction.

Error 09

Error 09 display times out. If the option is installed, Error 09 displayed may indicate an option malfunction.

Error 10

Error 10 turns off MODULATION OUTPUT/AUDIO INPUT.

Error 11

In dB RATIO, Error 11 is displayed when measurement result is 0 or negative. (The argument of the log function must be greater than 0.)
Error 12

Error 12 is enabled by Special Function 15.

Error 13

Error 13 usually only occurs when the power sensor is disconnected during an RF power measurement.

Error 14

Error 14 will not occur when using a sensor module (such as the HP 11722A) or a power sensor with an RF switch controlled by voltages accessed from the rear panel. (Refer to Remote Control RF Switch on page 3–109.)

Error 15

Refer to RF Power on page 3–74 for entry and edit information concerning calibration factors.

Error 17

Several conditions can cause this error:

- IF level too high for available range. Either Range Hold was selected or one of the measurement ranges (Special Functions 1 through 10) was user selected. Select AUTOMATIC OPERATION and try the measurement again.
- IF level too low when making a reference measurement. The reference is below 1.25V. Increase the source level to between 1.25V and 2.5V.
- Either a ratio measurement was attempted with an inadequate reference measurement or the reference was not measured before the ratio measurement was attempted. Take a reference measurement with the reference level between 1.25V and 2.5V.

Error 96

Error 96 corresponds to a display of two dashes (—). Error 96 can occur when no signal is applied or when Error 03 is disabled and the instrument is manually tuned where no signal is found. Error 96 (— —) turns off MODULATION OUTPUT/AUDIO INPUT.

</tr>
</tbody>
</table>

Error 20

When this error occurs during single-sideband noise measurements, the bandwidth entry was out-of-range. Usually it is unnecessary to enter a bandwidth for noise measurements. This bandwidth is established at the factory.
Error 24

Error 24 always causes the issuance of a Require Service message on the HP-IB.

Section 4
PERFORMANCE TESTS

4–1. INTRODUCTION
The procedures in this section test the instrument's electrical performance using the specifications of Table 1–1 as performance standards. All tests are performed without accessing the interior of the instrument. A simpler operational test is available in Section 3, Operation, under the title Basic Functional Checks.

NOTE

Unless otherwise noted, no warm-up period is required for the following tests.

Line voltage must be within +5% and −10% of nominal if the results of the performance tests are to be considered valid.

4–2. EQUIPMENT REQUIRED
Equipment required for the performance tests is listed in Table 1–3, Recommended Test Equipment. Any equipment that satisfies the critical specifications provided in the table may be substituted for the recommended model(s).

4–3. PERFORMANCE TEST RECORD
Results of the performance tests may be tabulated on the Performance Test Record at the end of the procedures. The Performance Test Record lists all of the tested specifications and their acceptable limits. The results, recorded at incoming inspection, can be used for comparison in periodic maintenance and troubleshooting and after repairs or adjustments.

4–4. CALIBRATION CYCLE
This instrument requires periodic verification of performance. Depending on the use and environmental conditions, the instrument should be checked using the following performance tests at least once every year.

4–5. ABBREVIATED PERFORMANCE TESTING
No abbreviation of performance testing is recommended.

</table>

<sup>(1)</sup> But not to exceed 50 kHz rates with rms detector.

<sup>(2)</sup> Peak residuals must be accounted for in peak readings. (Refer to Residual Noise Effects in Detailed Operating Instructions in Section 3.)

<sup>(3)</sup> For peak measurements only, AM accuracy may be affected by distortion generated by the Modulation Analyzer. In the worst case, this can decrease accuracy by 0.1% of reading for each 0.1% of distortion.

<sup>(4)</sup> For rms detector, add ±3% of reading.

<sup>(5)</sup> Flatness is the variation in indicated AM depth for constant depth on input signal.

<sup>(6)</sup> For optimum flatness, cables should be terminated with their characteristic impedance.
Description
AM accuracy is measured with the internal AM Calibrator, which produces approximately 33% AM at a 10 kHz rate. A low-residual AM source is connected to the input and the internal residual AM is measured. A source, which can produce wide-band, linear AM, is modulated at various AM rates and depths to measure distortion, flatness, and incidental FM and φM. A special AM/FM test source is required for these tests to assure that the AM source has adequate bandwidth, low distortion, low residual AM, and low incidental FM and φM.

Audio Synthesizer ............................................................ HP 3336C

![Diagram of test setup]

Figure 4–1. AM Performance Test Setup

NOTE
In the following procedure the RF modulation source can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer’s INPUT connector. The procedure is written for the latter case.

Procedure

AM Accuracy at 10 kHz Rate
1. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Connect the Modulation Analyzer’s CALIBRATION AM/FM OUTPUT to its INPUT.

NOTE
For greatest accuracy, allow the Modulation Analyzer to warm up for at least one-half hour.
2. On the Modulation Analyzer, press AM and then press CALIBRATE. Allow at least two readings (approximately 40 seconds) to pass. The display should read between 99 and 101%.

AM Calibration Factor 40% AM Range: 99 ______________________ 101%

3. Key in 2.2 SPCL to set the AM range to 100% AM. Allow at least two readings to pass. The display should read between 99 and 101%. Record this value for future reference.

AM Calibration Factor 100% AM Range: 99 ______________________ 101%

Residual AM

4. On the AM/FM test source, set the test mode switch to AM. Connect the test source AM output to the Modulation Analyzer's INPUT. (See Figure 4–1. Nothing should be connected to the test source's audio input.)

5. On the Modulation Analyzer, press FREQ and TRACK MODE. Tune the AM/FM test source's carrier frequency to approximately 12.5 MHz. Press TRACK MODE again to turn it off.

6. On the Modulation Analyzer, press AM. Key in 2.0 SPCL to set the modulation range to automatic. Set the other controls as follows:

   HP Filter .................................................. 50 Hz
   LP Filter .................................................. 3 kHz
   Detector .................................................. AVG

   The display should show 0.01% or less.

   Residual AM: ______________________ 0.01%

AM Distortion

7. Set the audio analyzer's oscillator to 20 kHz. Connect its output to the audio input of the AM/FM test source. (See Figure 4–1.)

NOTE

For this test, if the audio analyzer has floating input and output connectors, the low connector should be grounded. Connections should be made to the high input or high output connector.

8. Set the Modulation Analyzer controls as follows:

   HP Filter .................................................. All Off
   LP Filter .................................................. All Off
   Detector .................................................. PEAK+

9. Adjust the audio analyzer's oscillator level for a Modulation Analyzer display of 50% AM.
10. Connect the audio analyzer’s input to the Modulation Analyzer’s MODULATION OUTPUT/AUDIO INPUT. (See Figure 4-1.) Set the audio analyzer to measure the distortion on the 20 kHz signal at the MODULATION OUTPUT/AUDIO INPUT with 80 kHz of low-pass filtering (on the audio analyzer). The distortion should be 0.3% or less (−50 dB or less).

AM Distortion at 20 kHz Rate; 50% AM: ___________________________ 0.3%

11. Increase the audio analyzer’s oscillator level until the Modulation Analyzer reads 95% AM. Measure the distortion. The distortion should be 0.6% or less (−44 dB or less).

AM Distortion at 20 kHz Rate; 95% AM: ___________________________ 0.6%

12. Set the audio analyzer’s oscillator frequency to 20 Hz. Readjust the level, if necessary, for a Modulation Analyzer display of 95% AM. Measure the distortion. The distortion should be 0.6% or less.

AM Distortion at 20 Hz Rate; 95% AM: ___________________________ 0.6%

13. Decrease the audio analyzer’s oscillator level until the Modulation Analyzer reads 50% AM. Measure the distortion. The distortion should be 0.3% or less.

AM Distortion at 20 Hz Rate; 50% AM: ___________________________ 0.3%

**AM Flatness**

14. Set the audio synthesizer to 1 kHz at +1 dBm. Connect its output to the audio input of the AM/FM test source. (See Figure 4-1.) Fine adjust the audio synthesizer level for a Modulation Analyzer display of 80% AM.

**NOTE**

*Flatness of the audio synthesizer is critical for this test. If the audio synthesizer has leveling capability, switch it on.*

15. On the Modulation Analyzer, press AVG. Set RATIO on (with LOG/LIN set for a linear display). Set the audio synthesizer frequency as listed in the following table. For each setting, note the Modulation Analyzer’s display. The difference in readings between any two frequencies should be less than 0.8% REL.

**NOTE**

±0.3% of reading is equivalent to a difference of 0.6% between any pair of readings. ±1 digit at a nominal reading of 80.0 is about ±0.1% of the reading in the RATIO mode or ±0.2% for any pair of readings. The total limit is then 0.8%.

<table>

</table>

AM Flatness (Maximum Difference): ___________________________ 0.8% REL
AM Accuracy

16. On the Modulation Analyzer, press RATIO to turn it off. Press PEAK+. Key in 5.1 SPCL to set the audio detector time constant to slow.

17. Set the audio synthesizer frequency to 10 kHz. Set its level for a display of 80% AM times the calibration factor of step 3. (For example, if the calibration factor of step 3 is 100.4%, set the level for a display of 80.3% AM.)

18. On the Modulation Analyzer, key in 80 and press RATIO. Set the audio synthesizer to the frequencies shown in the following table (without changing the level). For each setting, the Modulation Analyzer's display should read between the limits indicated in the table.

<table>
<thead>
<tr>
<th>Audio Synthesizer Frequency (Hz)</th>

</tr>
</tbody>
</table>

AM Rejection

20. On the Modulation Analyzer, press RATIO to turn it off. Set the HP FILTER to 50 Hz and the LP FILTER to 3 kHz.

21. Set the audio synthesizer frequency to 1 kHz. Set its level for a Modulation Analyzer display of 50% AM.

22. On the Modulation Analyzer, press FM. Momentarily disconnect the audio input to the AM/FM test source and note the residual FM displayed on the Modulation Analyzer.

Residual FM; 455 kHz IF: __________________________ Hz

23. Reconnect the audio input of the AM/FM test source. Note the Modulation Analyzer's displayed FM. The displayed FM minus one-half the residual FM noted in step 22 should be 20 Hz peak or less.

AM Rejection (with FM); 455 kHz IF: __________________________ 20 Hz
24. On the Modulation Analyzer, key in 3.0 SPCL to set the IF back to 1.5 MHz. Repeat steps 22 and 23.

   Residual FM; 1.5 MHz IF: _______________ Hz

   AM Rejection (with FM); 1.5 MHz IF: _______________ 20 Hz

25. On the Modulation Analyzer, press £M. Momentarily disconnect the audio input to the AM/FM test source and note the residual £M displayed on the Modulation Analyzer.

   Residual £M; 1.5 MHz IF: _______________ rad

26. Reconnect the audio input of the AM/FM test source. Note the Modulation Analyzer's displayed £M. The displayed £M minus one-half the residual £M noted in step 25 should be 0.030 rad peak or less.

   AM Rejection (with £M); 1.5 MHz IF: _______________ 0.030 rad

<sup>(2)</sup> Peak residuals must be accounted for in peak readings. (Refer to Residual Noise Effects in Detailed Operating Instructions in Section 3.)

### Description
FM is measured with a very low-noise oscillator at the Modulation Analyzer's input. The resulting measured FM is the residual FM of the Modulation Analyzer's internal local oscillator. FM accuracy is measured with the internal FM Calibrator, which produces approximately 34 kHz peak deviation at a 10 kHz rate. A source, which can produce wide-band, linear FM, is modulated at various FM rates and deviations to measure distortion, flatness, and incidental AM. A special AM/FM test source is required for these tests to assure that the FM source has adequate bandwidth, low distortion, low residual FM, and low incidental AM.

### Equipment
AM/FM Test Source .................................................. HP 11715A
Audio Analyzer ...................................................... HP 8903B
Audio Synthesizer ................................................... HP 3336C

![Diagram of Modulation Analyzer with Audio Analyzer and Audio Synthesizer connected to AM/FM Test Source]

*Figure 4–2. FM Performance Test Setup*
NOTE

In the following procedure the RF modulation source can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer's INPUT connector. The procedure is written for the latter case.

Procedure

Residual FM

1. On the AM/FM test source, set the test mode to residual FM. Connect its low-residual (560 MHz) output to the Modulation Analyzer's INPUT. (See Figure 4-2.)

2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Set the other controls as follows:

   Measurement ................................................................. FM
   HP Filter ................................................................. 50 Hz
   LP Filter ................................................................. 3 kHz
   Detector ................................................................. AVG

The display should read 4 Hz or less.

   Residual FM at 560 MHz; 50 Hz to 3 kHz bandwidth: _______________ 4 Hz

NOTE

The equation for determining the residual FM limits is:

residual FM in Hz = 5.83 \times \text{carrier frequency in GHz} + 0.42 \text{ Hz}.

For a carrier of 560 MHz, the residual FM limit is 3.7 Hz. Allowing for one digit of uncertainty gives a limit of approximately 4 Hz.

FM Accuracy at 10 kHz Rate

3. Connect the Modulation Analyzer's CALIBRATE AM/FM OUTPUT to the INPUT. (See Figure 4-2.)

NOTE

For greatest accuracy, allow the Modulation Analyzer to warm up for at least one-half hour.

4. On the Modulation Analyzer, press CALIBRATE. Allow at least two readings (approximately 40 seconds) to pass. The display should read between 99 and 101%. Record this value for future reference.

   FM Calibration Factor; 40 kHz Modulation Range: 99 _______________ 101%
5. On the Modulation Analyzer, key in 2.3 SPCL to set the modulation range to 400 kHz. Allow at least two readings to pass. The display should read between 99 and 101%.

FM Calibration Factor; 400 kHz Modulation Range: 99 ____________________________ 101%

6. On the AM/FM test source, set the test mode to FM. Connect its FM÷4 output to the Modulation Analyzer's INPUT. (See Figure 4-2.)

7. Set the audio analyzer's oscillator to 10 kHz at 1V. Connect its output to the audio input of the AM/FM test source. (See Figure 4-2.)

NOTE
For this test, if the audio analyzer has floating input and output connectors, the low connector should be grounded. Connections should be made to the high input or high output connector.

8. On the Modulation Analyzer, press FREQ and TRACK MODE. Tune the AM/FM test source's carrier frequency to approximately 100 MHz. Press TRACK MODE again to turn it off.

9. On the Modulation Analyzer, press FM. Set LP FILTER to 15 kHz and DETECTOR to AVG. Key in 2.0 SPCL to set the modulation range to automatic.

10. Adjust the audio analyzer's oscillator level for a Modulation Analyzer display of 20 kHz average deviation. On the Modulation Analyzer, set RATIO on (with LOG/LIN set for a linear display).

11. Connect the FM÷32 output of the AM/FM test source to the Modulation Analyzer's INPUT without disturbing the AM/FM test source's controls. (See Figure 4-2.) Multiply the displayed ratio on the Modulation Analyzer by the calibration factor of step 4. (For example, if the display reads 12.52% REL and the calibration factor of step 4 is 100.4%, the result is 12.52 × 100.4 = 12.57% REL.) The result should be between 12.35 and 12.65% REL.

FM Accuracy; 4 kHz Modulation Range: 12.35 ____________________________ 12.65% REL

FM Distortion, Accuracy, and Rejection—1.5 MHz IF

12. Connect the FM÷4 output of the AM/FM test source to the Modulation Analyzer's INPUT. (See Figure 4-2.)

13. On the Modulation Analyzer, set all LP FILTERs to off, DETECTOR to PEAK+, and RATIO off.

14. Set the audio analyzer's oscillator frequency to 100 kHz. Set the level for a Modulation Analyzer display of 100 kHz peak deviation.

15. Connect the audio analyzer's input to the Modulation Analyzer's MODULATION OUTPUT/AUDIO INPUT. (See Figure 4-2.) Set the audio analyzer to measure the distortion on the 100 kHz signal at the MODULATION OUTPUT/AUDIO INPUT (all audio analyzer filters should be off). The distortion should be 0.1% or less (−60 dB or less).

FM Distortion at 100 kHz Rate; 100 kHz Peak Deviation: ____________________________ 0.1%
16. Set the audio synthesizer to 10 kHz at +5 dBm. Connect its output to the audio input of the AM/FM test source. (See Figure 4-2.) Fine adjust the level for a Modulation Analyzer display of 100 kHz times the calibration factor of step 5. (For example, if the calibration factor of step 5 is 100.4%, set the level for a display of 100.4 kHz.)

NOTE

Flatness of the audio synthesizer is critical for this test. If the audio synthesizer has leveling capability, switch it on.

17. Set the audio synthesizer to the frequencies in the following table. For each setting, the Modulation Analyzer's display should read between the limits indicated in the table.

<table>
<thead>
<tr>
<th>Audio Synthesizer Frequency (Hz)</th>

18. On the Modulation Analyzer, set HP FILTER to 50 Hz and LP FILTER to 3 kHz.

19. Set the audio synthesizer frequency to 1 kHz. Set the level for a Modulation Analyzer display of 50 kHz peak deviation.

20. On the Modulation Analyzer, press AM. Momentarily disconnect the audio input to the AM/FM test source and note the residual AM displayed on the Modulation Analyzer.

Residual AM: ________________ %

21. Reconnect the audio input of the AM/FM test source. Note the AM displayed on the Modulation Analyzer. The displayed AM minus one-half the residual AM noted in step 20 should be 0.2% or less.

FM Rejection at 1 kHz Rate; 50 kHz Peak Deviation: ________________ 0.2%

**FM Distortion, Accuracy, and Rejection—455 kHz IF**

22. Connect the FM±32 output of the AM/FM test source to the Modulation Analyzer's INPUT. (See Figure 4-2.)

23. On the Modulation Analyzer, key in 3.1 SPCL to set the IF to 455 kHz. Press FM.

24. Set the audio synthesizer level for a Modulation Analyzer display of 5 kHz peak deviation.

25. On the Modulation Analyzer, press AM. Momentarily disconnect the audio input to the AM/FM test source and note the residual AM displayed on the Modulation Analyzer.

Residual AM: ________________ %

26. Reconnect the audio input of the AM/FM test source. Note the AM displayed on the Modulation Analyzer. The displayed AM minus one-half the residual AM noted in step 25 should be 0.2% or less.

FM Rejection at 1 kHz Rate; 5 kHz Peak Deviation: ________________ 0.2%
27. On the Modulation Analyzer, press FM. Set all HP FILTERs to off and LP FILTER to >20 kHz.

28. Set the audio synthesizer level for a Modulation Analyzer display of 10 kHz peak deviation times the calibration factor of step 4. (For example, if the calibration factor of step 4 is 100.4%, set the level for a display of 10.04 kHz.)

29. Set the audio synthesizer to the frequencies shown in the following table. For each setting, the Modulation Analyzer's display should read between the limits indicated in the table.

(1) Peak residuals must be accounted for in peak readings. (Refer to Residual Noise Effects in Detailed Operating Instructions in Section 3.)
(2) For rms detector, add ±3% of reading.

Description

A signal with a known amount of phase modulation is generated by frequency modulating a carrier at a known peak deviation (as measured by the previously-calibrated Modulation Analyzer) and rate. The relationship between the peak phase deviation and peak frequency deviation is:

\[
\text{peak phase deviation} = \frac{\text{peak frequency deviation}}{\text{modulation rate}}
\]

The measured deviation is compared with the calculated deviation for several combinations of FM deviation and rate. The distortion is also measured. A special AM/FM test source is required for these tests to assure that the FM source has adequate bandwidth, low-distortion, and low residual FM.
Equipment

AM/FM Test Source ................................................. HP 11715A
Audio Analyzer ..................................................... HP 8903B
Audio Synthesizer .................................................. HP 3336C

Figure 4–3. °M Performance Test Setup

NOTE

In the following procedure the RF modulation source can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer’s INPUT connector. The procedure is written for the latter case.

Procedure

°M Accuracy

1. Perform Performance Test 2 FM.
2. On the AM/FM test source, set the test mode to FM. Connect its FM output to the Modulation Analyzer’s INPUT. (See Figure 4–3.)
3. Set the audio synthesizer to 200 Hz at −10 dBm. Connect its output to the audio input of the AM/FM test source. (See Figure 4–3.)
4. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press FREQ and TRACK MODE. Tune the AM/FM test source’s carrier frequency to approximately 400 MHz. Press TRACK MODE again to turn it off.
5. On the Modulation Analyzer, set the controls as follows:

Measurement ....................................................... FM
LP Filter ......................................................... >20 kHz
Detector ........................................................ AVG
6. Set the audio synthesizer frequency as shown in the following table. Set the Modulation Analyzer High Pass Filter as shown in the table. Set the audio synthesizer level to give the FM deviation shown in the table (as read on the Modulation Analyzer). After setting each FM deviation, press $\Phi M$. For each setting, the Modulation Analyzer’s display should read between the limits indicated in the table.

* Connect the FM 1/32 output of the AM/FM test source to the Modulation Analyzer's INPUT to make this measurement. (See Figure 4-3.) Press AUTOMATIC OPERATION, then $\Phi M$ to return the Measuring Receiver. If the resolution is not 0.001 rad, press $\Phi M$ again.

7. On the Modulation Analyzer, key in 3.1 SPCL to set the IF to 455 kHz. Press FM. On the AM/FM test source, connect the FM 1/4 output. (See Figure 4-3.) Set the audio synthesizer frequency as shown in the following table. Set the Modulation Analyzer High Pass Filter as shown in the table. Set the audio synthesizer level to give the FM deviation shown in the table. After setting each FM deviation, press $\Phi M$. For each setting, the Modulation Analyzer’s display should read between the limits indicated in the table.

$\Phi M$ Distortion

8. Connect the FM output of the AM/FM test source to the Measuring Receiver’s INPUT. (See Figure 4-3.) Press AUTOMATIC OPERATION on the Modulation Analyzer.

9. Set the audio analyzer’s oscillator to 1 kHz. Connect its output to the audio input of the AM/FM test source. (See Figure 4-3.)

NOTE

For this test, if the audio analyzer has floating input and output connectors, the low connector should be grounded. Connections should be made to the high input or high output connector.

10. On the Modulation Analyzer, press $\Phi M$. Set DETECTOR to PEAK+. Set HP FILTER to 300 Hz. Set LP FILTER to 15 kHz.

11. Adjust the audio analyzer’s oscillator level to give a display of 400 rad peak deviation.
12. Connect the audio analyzer’s input to the Modulation Analyzer’s MODULATION OUTPUT/AUDIO INPUT. (See Figure 4–3.) Set the audio analyzer to measure the distortion on the 1 kHz signal at the MODULATION OUTPUT/AUDIO INPUT. Set the high-pass filter on the audio analyzer to 400 Hz. The distortion should be 0.1% (−60 dB) or less.

ΦM Distortion at 1 kHz Rate; 400 rad Peak Deviation; 1.5 MHz IF: _______________ 0.1%

13. Reduce the audio analyzer’s oscillator level to give a display of 40 rad peak deviation.

14. On the Modulation Analyzer, key in 3.1 SPCL. The distortion measured on the audio analyzer should be 0.1% or less.

ΦM Distortion at 1 kHz Rate; 40 rad Peak Deviation; 455 kHz IF: _______________ 0.1%

$^{(1)}$ The >20 kHz low-pass filter is intended for minimum overshoot squarewave modulation.

Description

A signal is frequency modulated by a source which is known to have FM which is flat with rate. The flatness of the demodulated signal is then measured for various modulation filters.

NOTE

Flatness of the audio synthesizer is critical for this test. If the audio synthesizer has leveling capability, switch it on.

Equipment

AM/FM Test Source ................................................................. HP 11715A
Audio Synthesizer ............................................................... HP 3336C

Procedure

NOTE

In the following procedure the RF modulation source can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer's INPUT connector. The procedure is written for the latter case.
1. Connect the equipment as shown in Figure 4-4.
2. On the AM/FM test source, set the test mode to FM.
3. Set the audio synthesizer to 200 Hz at +6 dBm.
4. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press FREQ and TRACK MODE. Tune the AM/FM test source’s carrier frequency to approximately 100 MHz. Press TRACK MODE again to turn it off.
5. On the Modulation Analyzer, press MHz to center the instrument’s tuning. Set the other controls as follows:

   Measurement .......................................................... FM
   Detector .................................................................. AVG

6. Set the audio synthesizer level to give a display of approximately 25 kHz average deviation.
7. Set the audio synthesizer frequency to the frequencies shown in the following table. For each setting, set RATIO on the Modulation Analyzer to off, set all HP or LP FILTERs to off, then set RATIO to on (with LOG/LIN set for a linear display), and insert the filter indicated. For each setting, the Modulation Analyzer’s display should read between the limits indicated in the table.

$^{(1)}$ For demodulated signals, the residual noise generated by the Modulation Analyzer must be accounted for in distortion measurements (that is, residual AM, FM, or $\Phi$M).

4–20  Performance Test 5
Description

All audio measurements are made on external audio signals. Level accuracy is measured by comparing the voltage reading on the Modulation Analyzer with the output from a more accurately set audio oscillator. Residual distortion and noise is measured by making a distortion measurement on a low-distortion oscillator. Measurements must be made at several frequencies within the notch filter range to verify proper nulling of the fundamental. Distortion accuracy is measured by summing a low-distortion output from one oscillator with the output of an oscillator which is set to generate a second through fifth harmonic of known magnitude. The audio counter is checked by counting the signal from a audio frequency synthesizer set to both high and low levels.

Equipment

Audio Analyzer ................................................................. HP 8903B
Audio Synthesizer ............................................................ HP 3336C

Procedure

Audio RMS Accuracy

1. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 30.0 SPCL to set the Modulation Analyzer to measure external audio rms level.

2. Set the audio synthesizer to 50 Hz at +16.54 dBm. (To produce 3V, the synthesizer is set to deliver 1.5V or +16.54 dBm into 50Ω; this becomes 3V when applied to the 100 kΩ audio input of the Modulation Analyzer.)

3. Connect the audio synthesizer output to the Modulation Analyzer's MODULATION OUTPUT/AUDIO INPUT connector.

4. Set the audio synthesizer to the frequencies shown in the following table. For each setting, the Modulation Analyzer's display should read between the limits indicated in the table.

<table>
<thead>
<tr>

Residual Noise and Distortion

8. Set the audio synthesizer to 380 Hz at -13 dBm (100 mV at the audio input).

9. On the Modulation Analyzer, press S (shift) then AUDIO DISTN. Press the blue key then press 400 Hz DISTN (the PEAK- key).

10. Slowly step the audio synthesizer up in frequency to 420 Hz using 2 Hz steps or finer. Note the highest distortion reading displayed on the Modulation Analyzer. The highest reading should not exceed 0.3%.

   Maximum Residual Distortion; 400 Hz Input at 100 mV: ___________ 0.3%

11. Increase the audio synthesizer level to +16.5 dBm. Slowly step the audio synthesizer down in frequency to 380 Hz using 2 Hz steps or finer. Note the highest distortion reading displayed on the Modulation Analyzer. The highest reading should not exceed 0.3%.

   Maximum Residual Distortion; 400 Hz Input at 3V: ___________ 0.3%

12. Set the audio synthesizer frequency to 950 Hz.

13. On the Modulation Analyzer, press the blue key then press 1 kHz DISTN (the PEAK+ key).

14. Slowly step the audio synthesizer up in frequency to 1050 Hz using 5 Hz steps or finer. Note the highest distortion reading displayed on the Modulation Analyzer. The highest reading should not exceed 0.3%.

   Maximum Residual Distortion; 1 kHz Input at 3V: ___________ 0.3%

15. Decrease the audio synthesizer level to -13 dBm. Slowly step the audio synthesizer down in frequency to 950 Hz using 5 Hz steps or finer. Note the highest distortion reading displayed on the Modulation Analyzer. The highest reading should not exceed 0.3%.

   Maximum Residual Distortion; 1 kHz Input at 100 mV: ___________ 0.3%
Distortion Accuracy

16. On the audio analyzer, set its output float switch to the float position. Set the audio analyzer’s oscillator to 1 kHz at 1V.

17. Set the audio synthesizer to 2 kHz at a level as low as possible without switching the instrument off (but less than −50 dBm). Connect the audio analyzer and audio synthesizer as shown in Figure 4–5. Note that the audio synthesizer is connected to the floating low output of the audio analyzer’s output. (This has the effect of summing the two outputs.)

Figure 4–5. Distortion Accuracy Performance Test Setup

18. On the Modulation Analyzer, key in 30.0 SPCL to set the Modulation Analyzer to measure external audio rms level. (Note that the display reads approximately 1V.) Now set RATIO to on.

19. Set the audio analyzer’s oscillator level to 0V or a level as low as possible without switching the instrument off (but at most 10 mV).

20. Increase the audio synthesizer’s level until the Modulation Analyzer’s display reads between 99 and 101%.

21. Switch the audio synthesizer’s level down exactly 40 dB. Set the audio analyzer’s oscillator level back to 1V.

22. On the Modulation Analyzer, press S (shift) then AUDIO DISTN.

23. Set the audio synthesizer’s frequency as shown in the following table without changing the audio synthesizer’s amplitude. For each setting, the Modulation Analyzer’s display should read between the limits indicated in the table.

<table>
<thead>

</tbody>
</table>

Description

The power from an external 1 mW power reference is measured with a power sensor and the power meter of the Modulation Analyzer. The same power meter and sensor are then used to measure the power from the Modulation Analyzer's power reference.

NOTE

Due to accuracy limitations of this test method, the power level can only be verified to within ±1.9%. Greater accuracy can be obtained by using a recently calibrated external power reference or by following the procedure in Performance Test 7—Power Reference Accuracy (Using DC Substitution).

Equipment

Power Reference ............................................................... HP 435A Opt K05
Sensor Module ............................................................... HP 11722A

Procedure

1. Connect the input of the sensor module (or a compatible power sensor connected to the Modulation Analyzer’s SENSOR input) to the output of the external power reference.

2. On the Modulation Analyzer, press RF POWER. Press RATIO and check that LOG/LIN is in the linear mode. (The display should read between 99.9 and 100.1% REL.)

3. Connect the power sensor/input switch to the CALIBRATION RF POWER OUTPUT connector of the Modulation Analyzer. The display should read 98.1 and 101.9% REL.

RF Power Reference Accuracy: 98.1 ________________________ 101.9% REL

</tr>
</tbody>
</table>

Description

The power from the power reference oscillator is measured by a method known as dc substitution. In this method a power-sensing thermistor is placed in one arm of a self-balancing, dc resistance bridge. With no power applied, the dc voltage supplying the top of the bridge is automatically adjusted until the thermistor heats to the temperature that produces the resistance required to bring the bridge into balance. When RF power is applied to the thermistor, the thermistor heats up and momentarily unbalances the bridge. The self-balancing circuits then readjust the supply voltage to the bridge to re-balance it. A second bridge, which senses only the ambient temperature, is employed to compensate for measurement drift. Careful measurement of the bridge dc voltages provides a way to determine the amount of RF power applied to the thermistor to a higher degree of accuracy than can be obtained by direct reading of the power meter.

NOTE

The power level can be measured to an accuracy of ±1.2% by this procedure. A simpler, but less accurate method for measuring the power reference can be found in the preceding Performance Test 6—Power Reference (Using Reference Comparison).

Equipment

- Digital Voltmeter ........................................... HP 3455A
- Power Meter .................................................... HP 432A
- Thermistor Mount ............................................ HP 478A Opt H75

Procedure

1. With the HP 432A Power Meter switched off and the thermistor interconnect cable connected to it but not to the thermistor mount, measure the resistance between the center conductor of the rear-panel VRF connector and pin 1 (the first pin to the right of the key slot) on the thermistor end of the interconnect cable. Record the value of the mount resistance for future reference. (It should be approximately 200Ω.)

   Mount Resistance (R):  _____________ Ω

2. Connect the equipment as shown in Figure 4–6. The input of the digital voltmeter should be floating. The positive input of the voltmeter should be connected to the rear-panel VCOMP
connector of the HP 432A Power Meter, the negative input to the VRF connector. Switch the equipment on and let it warm up for at least 30 minutes.

NOTE

From this point on do not handle the HP 478A in order to maintain its thermal stability.

![Diagram of test setup](image)

**Figure 4–6. Power Reference Performance Test Setup**

3. On the Modulation Analyzer, key in 45.0 SPCL to switch the power reference off.
4. Set the HP 432A Power Meter RANGE to COARSE ZERO and adjust the front-panel COARSE ZERO to obtain a zero meter indication.
5. Fine zero the HP 432A Power Meter on the most sensitive range, then set the RANGE switch to 1 mW (0 dBm).
6. Observe the voltage reading on the voltmeter. If the reading is greater than 400 μV, press and hold the FINE ZERO switch on the HP 432A Power Meter and adjust COARSE ZERO so that the voltmeter reads less than 200 μV then release the FINE ZERO switch. Record the voltmeter reading for future reference.

\[ V_{COMP} - V_{RF} \text{ with No Power (V₀): } \text{_______________ Vdc} \]

**NOTE**

Steps 6, 7, and 8 should be performed as quickly as possible to minimize drift.

7. On the Modulation Analyzer, key in 45.16 SPCL. Record the voltmeter reading.

\[ V_{COMP} - V_{RF} \text{ with 1 mW (V₁): } \text{_______________ Vdc} \]

8. Connect the voltmeter to read \( V_{COMP} \) (with respect to chassis ground) on the HP 432A Power Meter. (The voltmeter’s negative input should connect to chassis ground.) Record the voltmeter reading.

\[ V_{COMP} \text{ with 1 mW: } \text{_______________ Vdc} \]
9. Compute the power \( P \) in watts from the equation

\[
P = \frac{2V_{COMP}(V_1 - V_0) + V_0^2 - V_1^2}{4RH}
\]

where \( H \) is the effective efficiency of the thermistor mount at 50 MHz as read from its label and \( R \) is the resistance measured in step 1. The computed power should be between 0.988 and 1.012 mW.

RF Power Reference Power: 0.988 .......................... 1.012 mW

(1) Using Recorder Output. Using front-panel display, add ±1 count of least-significant digit.
(2) Decrease by a factor of ten for each higher range.

Description

A power meter range calibrator is used to check the range-to-range error, in-range linearity, and zeroing integrity of the power meter circuits. RF power ranging is simulated by a precision voltage divider in the range calibrator.

Equipment

Range Calibrator.................. HP 11683A

Procedure

Zero Set
1. Connect the power meter output of the range calibrator to the Modulation Analyzer’s SENSOR input.
2. On the range calibrator, set the function to standby, polarity to normal, and range to 1 mW.
3. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press RF POWER. Press ZERO and wait for the instrument to zero.

NOTE

If Error 15 is displayed, press 100 then the blue key then the % CAL FACTOR key (the MHz key) to enter a dummy calibration factor of 100%.

4. On the Modulation Analyzer, key in the special functions indicated in the following table. For each setting the Modulation Analyzer’s display should read as indicated in the table. (Take the average of several readings. Ignore the RECAL and UNCAL annunciators.)
**Serial Prefix 2305A to 2450A:**

**Range-to-Range Error**

5. On the range calibrator, set the function to calibrate.

6. On the Modulation Analyzer, key in 10.0 SPCL to set the power meter ranging to automatic. Press CALIBRATE then press the blue key then press SAVE CAL (again, the CALIBRATE key). This normalizes the power reading to 1 mW. (The CALIBRATE key light should be on.)

7. On the Modulation Analyzer, key in the Special Functions listed in the following table. For each setting, set the range calibrator to the range indicated in the table. The reading on the Modulation Analyzer should be within the limits shown.

<tbody>
<tr>
<td>RF POWER</td>
<td></td>
<td>using HP 11722A Sensor Module</td>
</tr>
<tr>
<td>Input SWR</td>
<td>&lt;1.15</td>
<td></td>
</tr>
</tbody>
</table>

Description

Input SWR is determined by measuring return Loss. Measurements are made at the input of a power sensor or sensor module connected to the Modulation Analyzer. The sensor input is driven by a signal generator through an SWR bridge. The reflected power is measured by a spectrum analyzer. A reference line is first established by disconnecting the output of the SWR bridge to create a high-reflection, open circuit.

Equipment

- Attenuator, 6 dB ....................................................... HP 8491A Option 006
- RF Spectrum Analyzer .................................................. HP 8559A/182T
- Sensor Module .......................................................... HP 11722A
- Signal Generator ....................................................... HP 8640B Option 002
- SWR Bridge ............................................................... Wiltron 60NF50

![Diagram](image)

Figure 4-7. SWR Performance Test Setup
NOTE

The log display accuracy of the spectrum analyzer may be inadequate for this test. If any data points in the following procedure appear to be near or out of limits, check the amplitude calibration of the spectrum analyzer as described in its manual and use the data obtained there to correct the results in this procedure.

If a tracking generator that is compatible with the RF spectrum analyzer is substituted for the signal generator, a swept measurement can be made.

Procedure

1. Connect the equipment as shown in Figure 4-7. Connect the 6 dB attenuator directly to the RF input of the SWR bridge. Do not connect anything to the device-under-test input of the SWR bridge at this time.
2. Set the signal generator level to +3 dBm CW.
3. Set the spectrum analyzer to sweep 0 to 1 GHz. Set the display for 10 dB per vertical division.
4. With the sensor module disconnected from the SWR bridge, tune the signal generator from 0.1 to 1300 MHz and note the level of the signal. Adjust the spectrum analyzer's reference level, as needed, to set the average level of the signal to a convenient graticule reference. Re-sweep the signal generator and note the reference on the display.

NOTE

If the signal generator or spectrum analyzer is incapable of complete coverage of the frequency range, use whatever range is available. If the spectrum analyzer has variable persistence or storage capability, use it to store the reference line.

5. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press RF POWER. Connect the sensor module to the SWR bridge. (See Figure 4-7.)
6. Re-sweep the signal generator and observe the level of the signal on the spectrum analyzer. At all frequencies between 2.5 and 1300 MHz the signal should be 23 dB below the reference signal. (Repeat the above steps and adjust the spectrum analyzer sweep, as required, to gather data for the highest and lowest frequencies.)

12.5 kHz Filter Shape (Option 032)  
25 kHz Filter Shape (Option 033)

Description

The accuracy of the high-selectivity filters is tested by feeding a 455 kHz CW signal directly into the IF via the front-panel input connector. As the frequency of the input is changed, the shape of the IF is determined.

NOTE

This procedure tests only instruments with the 12.5 kHz Adjacent Channel Filter (Option 032) or 25 kHz Adjacent Channel Filter (Option 033) or both. Depending on the combination of these filters with the other available filter options (Options 035 and 037), either filter can be defined as the "wide" or "narrow" filter with regards to Special Function 24, which is used in the procedure. Follow the procedure or procedures which apply to the instrument's particular option combination.

Equipment

Signal Generator ............................................................. HP 8640B or HP 3336C
Procedure

NOTE

In the following procedure the signal generator can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer’s INPUT connector. The procedure is written for the latter case.

Initial Setup
1. Set the signal generator to 455.0 kHz CW at +3 dBm. Connect the signal generator’s output to the Modulation Analyzer’s INPUT. Allow the equipment to warm up at least one-half hour.

"Wide" Filter Test—Option Combination 032 and 037
2. On the Modulation Analyzer, key in the following:
   a. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument.
   b. Key in 100 MHz to inhibit automatic tuning.
   c. Key in 24.0 SPCL to initialize the high-selectivity level measurement.
   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.1 SPCL to read the IF level.
3. Slowly tune the frequency of the signal generator up and down until the peak reading is found.
4. On the Modulation Analyzer, key in 24.1 SPCL and 24.2 SPCL to establish and display the current IF level as a level reference. (The display should read 0 dB.)
5. Tune the signal generator down until the first minimum is found. The display should read −2 dB or higher (that is, between −2 and 0 dB).

   12.5 kHz Filter: Loss at First Minimum: −2 dB

6. Tune the signal generator down until the display reads −6.00 dB. Record the signal generator’s frequency.

   12.5 kHz Filter: Lower 6 dB Frequency: ______________ kHz

7. Tune the signal generator down 1.6 kHz. The display should read −30 dB or less (that is, more negative).

   12.5 kHz Filter: Loss at 1.6 kHz Below Lower 6 dB Corner: ______________ −30 dB

8. Tune the signal generator down another 3 kHz. The display should read −80 dB or less.

   12.5 kHz Filter: Loss at 4.6 kHz Below Lower 6 dB Corner: ______________ −80 dB

9. Tune the signal generator up until the display reads 0 dB, then continue on until the display reads −6.00 dB. Record the signal generator’s frequency.

   12.5 kHz Filter: Upper 6 dB Frequency: ______________ kHz

10. Subtract the reading of step 9 from the reading of step 6. The difference should be between 6.4 and 10.4 kHz.

   12.5 kHz Filter: 6 dB Bandwidth: 6.4 ______________ 10.4 kHz
11. Tune the signal generator up 12 kHz above the frequency recorded in step 6. The display should read \(-30\) dB or less.

12.5 kHz Filter: Loss at 12 kHz Above Lower 6 dB Corner: \(-30\) dB

12. Tune the signal generator up another 3 kHz. The display should read \(-80\) dB or less.

12.5 kHz Filter: Loss at 15 kHz Above Lower 6 dB Corner: \(-80\) dB

"Wide" Filter Test—Option Combination 032 and 033 or 033 and 037

13. Perform step 1, then on the Modulation Analyzer, key in the following:
   a. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument.
   b. Key in 100 MHz to inhibit automatic tuning.
   c. Key in 24.0 SPCL to initialize the high-selectivity level measurement.
   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.1 SPCL to read the IF level.

14. Slowly tune the frequency of the signal generator up and down until the peak reading is found.

15. On the Modulation Analyzer, key in 24.1 SPCL and 24.2 SPCL to establish and display the current IF level as a level reference. (The display should read 0 dB.)

16. Tune the signal generator down until the first minimum is found. The display should read \(-2\) dB or higher (that is, between \(-2\) and \(0\) dB).

25 kHz Filter: Loss at First Minimum: \(-2\) dB

17. Tune the signal generator down until the display reads \(-6.00\) dB. Record the signal generator’s frequency.

25 kHz Filter: Lower 6 dB Frequency: \(\underline{kHz}\)

18. Tune the signal generator down 1.6 kHz. The display should read \(-30\) dB or less (that is, more negative).

25 kHz Filter: Loss at 1.6 kHz Below Lower 6 dB Corner: \(-30\) dB

19. Tune the signal generator down another 3 kHz. The display should read \(-80\) dB or less.

25 kHz Filter: Loss at 4.6 kHz Below Lower 6 dB Corner: \(-80\) dB

20. Tune the signal generator up until the display reads 0 dB, then continue on until the display reads \(-6.00\) dB. Record the signal generator’s frequency.

25 kHz Filter: Upper 6 dB Frequency: \(\underline{kHz}\)

21. Subtract the reading of step 20 from the reading of step 17. The difference should be between 12.4 and 16.9 kHz.

25 kHz Filter: 6 dB Bandwidth: 12.4 \(\underline{16.9\ kHz}\)

22. Tune the signal generator up 18.5 kHz above the frequency recorded in step 17. The display should read \(-30\) dB or less.

25 kHz Filter: Loss at 18.5 kHz Above Lower 6 dB Corner: \(-30\) dB
23. Tune the signal generator up another 3 kHz. The display should read −80 dB or less.

25 kHz Filter: Loss at 21.5 kHz Above Lower 6 dB Corner: −80 dB

"Narrow" Filter Test—Option Combination 032 and 033 or 032 and 035

24. Perform step 1, then on the Modulation Analyzer, key in the following:
   a. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument.
   b. Key in 100 MHz to inhibit automatic tuning.
   c. Key in 24.0 SPCL to initialize the high-selectivity level measurement.
   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.3 SPCL to read the IF level.

25. Slowly tune the frequency of the signal generator up and down until the peak reading is found.

26. On the Modulation Analyzer, key in 24.3 SPCL and 24.4 SPCL to establish and display the current IF level as a level reference. (The display should read 0 dB.)

27. Tune the signal generator down until the first minimum is found. The display should read −2 dB or higher (that is, between −2 and 0 dB).

12.5 kHz Filter: Loss at First Minimum: −2 dB

28. Tune the signal generator down until the display reads −6.00 dB. Record the signal generator’s frequency.

12.5 kHz Filter: Lower 6 dB Frequency: kHz

29. Tune the signal generator down 1.6 kHz. The display should read −30 dB or less (that is, more negative).

12.5 kHz Filter: Loss at 1.6 kHz Below Lower 6 dB Corner: −30 dB

30. Tune the signal generator down another 3 kHz. The display should read −80 dB or less.

12.5 kHz Filter: Loss at 4.6 kHz Below Lower 6 dB Corner: −80 dB

31. Tune the signal generator up until the display reads 0 dB, then continue on until the display reads −6.00 dB. Record the signal generator’s frequency.

12.5 kHz Filter: Upper 6 dB Frequency: kHz

32. Subtract the reading of step 31 from the reading of step 28. The difference should be between 6.4 and 10.4 kHz.

12.5 kHz Filter: 6 dB Bandwidth: 6.4 10.4 kHz

33. Tune the signal generator up 12 kHz above the frequency recorded in step 28. The display should read −30 dB or less.

12.5 kHz Filter: Loss at 12 kHz Above Lower 6 dB Corner: −30 dB

34. Tune the signal generator up another 3 kHz. The display should read −80 dB or less.

12.5 kHz Filter: Loss at 15 kHz Above Lower 6 dB Corner: −80 dB
“Narrow” Filter Test—Option Combination 033 and 035

35. Perform step 1, then on the Modulation Analyzer, key in the following:
   a. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to
      preset the instrument.
   b. Key in 100 MHz to inhibit automatic tuning.
   c. Key in 24.0 SPCL to initialize the high-selectivity level measurement.
   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.3 SPCL to read the IF level.

36. Slowly tune the frequency of the signal generator up and down until the peak reading is found.

37. On the Modulation Analyzer, key in 24.3 SPCL and 24.4 SPCL to establish and display the
    current IF level as a level reference. (The display should read 0 dB.)

38. Tune the signal generator down until the first minimum is found. The display should read –2 dB
    or higher (that is, between –2 and 0 dB).

    25 kHz Filter: Loss at First Minimum: –2 dB

39. Tune the signal generator down until the display reads –6.00 dB. Record the signal generator’s
    frequency.

    25 kHz Filter: Lower 6 dB Frequency: ______________________ kHz

40. Tune the signal generator down 1.6 kHz. The display should read –30 dB or less (that is, more
    negative).

    25 kHz Filter: Loss at 1.6 kHz Below Lower 6 dB Corner: ______________________ –30 dB

41. Tune the signal generator down another 3 kHz. The display should read –80 dB or less.

    25 kHz Filter: Loss at 4.6 kHz Below Lower 6 dB Corner: ______________________ –80 dB

42. Tune the signal generator up until the display reads 0 dB, then continue on until the display reads
    –6.00 dB. Record the signal generator’s frequency.

    25 kHz Filter: Upper 6 dB Frequency: ______________________ kHz

43. Subtract the reading of step 42 from the reading of step 39. The difference should be between
    12.4 and 16.9 kHz.

    25 kHz Filter: 6 dB Bandwidth: 12.4 ______________________ 16.9 kHz

44. Tune the signal generator up 18.5 kHz above the frequency recorded in step 39. The display should
    read –30 dB or less.

    25 kHz Filter: Loss at 18.5 kHz Above Lower 6 dB Corner: ______________________ –30 dB

45. Tune the signal generator up another 3 kHz. The display should read –80 dB or less.

    25 kHz Filter: Loss at 21.5 kHz Above Lower 6 dB Corner: ______________________ –80 dB

</tbody>
</table>

Description

This test checks the relative accuracy of the selective power measurement mode. The linearity of the IF rms detector (including the linearity of the internal dc voltmeter) is checked first. Linearity is measured by feeding a 455 kHz signal directly into the IF via the front-panel connector. The level is set to produce a signal that is near the upper measurement limit of the detector, a level reference is set, and the range settings held. The signal level is then decreased by precisely 5 dB, and the drop in displayed level is compared against the decrease in level.

IF gain step accuracy is measured by increasing the attenuation of the attenuator in 5 dB steps and comparing the displayed reading with the increase in attenuation.

Equipment

Signal Generator ................................................................. HP 3336C

Procedure

NOTE

In the following procedure the signal generator can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer’s INPUT connector. The procedure is written for the latter case.

Detector Linearity

1. Set the signal generator to 455 kHz CW at +3 dBm. Connect the signal generator’s output to the Modulation Analyzer’s INPUT. Allow the equipment to warm up at least one-half hour.
2. On the Modulation Analyzer, key in the following:
   a. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to
      preset the instrument.
   b. Key in 100 MHz to inhibit automatic tuning.
   c. Key in 24.0 SPCL to initialize the high-selectivity level measurement.
   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.1 SPCL to read the IF level.
   f. Key in 50.6 SPCL to select and display the output of the IF rms detector and to inhibit IF
      ranging.

3. Adjust the level of the signal generator for a displayed reading of 2.500.

4. Decrease the signal generator level by exactly 5 dB. Divide the displayed reading by 1.406 and
   record the result.

   IF RMS Detector Linearity: ________________

IF Gain Accuracy

5. On the Modulation Analyzer, key in 0.250 SPCL, 0.2 S (Shift) 4 S 4 SPCL, and 0.2 S 30 SPCL
   to set the IF gain to 0 dB. Key in 50.6 SPCL.

6. Increase the signal generator level for a displayed reading of 1.000.

7. Decrease the signal generator level by the exact amount indicated in the following table. For each
   setting, key in the Special Function(s) indicated, then key in 50.6 SPCL. Multiply the displayed
   result by the result of step 4. The computed result should be between 0.944 and 1.059 (that is,
   ±0.5 dB).

   d. Key in 3.1 SPCL to remove the RF input high-pass filter.
   e. Key in 24.1 SPCL to read the IF level.
   f. Key in 49.C SPCL (C is yellow shift key and digit 2) to select and display the output of the
      IF rms detector and to inhibit IF ranging.

3. Adjust the level of the signal generator for a displayed reading of 2.500.

4. Decrease the signal generator level by exactly 5 dB. Divide the displayed reading by 1.406 and
   record the result.

   IF RMS Detector Linearity: ______________________

IF Gain Accuracy

5. On the Modulation Analyzer, key in 0.390 SPCL, 0.3 S (Shift) 4 S 4 SPCL, and 0.3 S 30 SPCL
   to set the IF gain to 0 dB. Key in 49.C SPCL.

6. Increase the signal generator level for a displayed reading of 1.000.

7. Decrease the signal generator level by the exact amount indicated in the following table. For each
   setting, key in the Special Function(s) indicated, then key in 49.C SPCL. Multiply the displayed
   result by the result of step 4. The computed result should be between 0.944 and 1.059 (that is,
   ±0.5 dB).

Section 5
ADJUSTMENTS

5–1. INTRODUCTION

This section contains adjustments and checks that assure peak performance of the Modulation Analyzer. The instrument should be readjusted after repair or failure to pass a performance test. Allow a 30 minute warm-up prior to performing the adjustments. Removing the top cover is the only disassembly required for most adjustments.

To determine which performance tests and adjustments to perform after a repair, refer to paragraph 5–5, Post-Repair Tests, Adjustments, and Checks.

5–2. SAFETY CONSIDERATIONS

This section contains information, cautions, and warnings which must be followed for your protection and to avoid damage to the equipment.

**WARNING**

Adjustments described in this section are performed with power supplied to the instrument and with protective covers removed. Maintenance should be performed only by service trained personnel who are aware of the hazard involved (for example, fire and electrical shock). Where maintenance can be performed without power applied, the power should be removed.

Removal of the Modulation Analyzer’s bottom cover is not necessary to perform these adjustments. However, if the bottom cover is removed, hazardous voltage (~120 Vac) is accessible.

A pin-to-pin voltage difference of 55 Vdc may be found on many of the Modulation Analyzer’s circuit board connectors. Be careful while working on the circuit boards with power supplied to the instrument.

If a circuit board is placed on an extender board, the possibility of coming in contact with 55 Vdc is greatly increased. Be careful while working on the circuit boards with power supplied. Work with one hand. Do not touch the extender board.

5–3. EQUIPMENT REQUIRED

Each adjustment procedure contains a list of required test equipment. The test equipment is identified by callouts in the test setup diagrams where included.

If substitutions must be made for the specified test equipment, refer to Table 1–3 in the Operating Manual for the minimum specifications. It is important that the test equipment meet the critical specifications listed in the table if the Modulation Analyzer is to meet its performance requirements.
5–4. FACTORY-SELECTED COMPONENTS

Factory-selected components are identified on the schematics and parts list by an asterisk (*) which follows the reference designator. The normal value or range of the components is shown. The *Manual Changes* sheets will provide updated information pertaining to the selected components. Table 5–1 lists the reference designator, the criterion used for selecting a particular value, the normal value range, and the service sheet where the component part is shown.

5–5. POST-REPAIR TESTS, ADJUSTMENTS, AND CHECKS

Table 5–2 lists the performance tests, adjustments, and checks needed to calibrate or verify calibration of a repaired assembly. The tests, adjustments, and checks are classified by assembly repaired.

The table is also useful as a cross reference between performance tests and assemblies when the failure is a specification that is slightly out of limits.

For all repairs, perform the *Basic Functional Checks* in Section 3, *Adjustment 1 — Power Supply* (but only adjust the +15V supply if it is out of limits), and the *Adjustment 2 — Internal Reference Frequency*. The *Basic Functional Checks* utilize automatic tuning and measurement which exercises nearly every circuit in the instrument (except the Remote Interface Assembly).

5–6. RELATED ADJUSTMENTS

The procedures in this section can be done in any order, but it is advisable to check the power supply voltages and time base reference first.

 Adjustment 1

POWER SUPPLY
• Service Sheets 31 and 32

Description
The +15V supply is adjusted, and the other supplies, which are dependent upon it, are checked.

Equipment
Digital Voltmeter ................................................................. HP 3455A

Procedure
1. Set the voltmeter to measure +15 Vdc. Connect its input to A10TP3 (+15V SW).
2. Adjust A10R24 (+15V) for +14.99 to +15.01 Vdc at A10TP3.
3. Check the other supplies with the voltmeter as indicated in the following table.

INTERNAL REFERENCE FREQUENCY

- Service Sheets 22 and 31

**Description**

An oscilloscope, triggered by an external reference, is used to monitor the internal reference frequency. The internal reference frequency is adjusted for a stationary waveform on the oscilloscope.

**Equipment**

| Frequency Standard | House Standard | Oscilloscope | HP 1740A |

**Figure 5–1. Internal Reference Frequency Adjustment Test Setup**

**Procedure**

1. Connect the equipment as shown in Figure 5–1. Allow the equipment to warm up for 15 minutes. For Option 002, a warm-up of the Modulation Analyzer of several days with covers on is recommended.

2. Set the oscilloscope's vertical sensitivity to view the Modulation Analyzer's time base output. Set its horizontal scale for 10 μs per division. Set the oscilloscope to trigger externally.

3. Adjust A11C14 (10 MHZ REF) or, for Option 002, Y1 (COARSE and FINE) for a stationary waveform. If adjusting A11C14, use a totally non-metallic adjustment tool.

**NOTE**

Movement of the waveform to the right at a rate of one division per second means that the Modulation Analyzer's time base is low by 0.1 ppm.

If the frequency of the internal reference is quite far off, the oscilloscope display may be difficult to interpret. In that case, connect the frequency standard directly to the Modulation Analyzer's INPUT, press FREQ, and adjust the internal reference frequency for a display equal to the standard's frequency, then begin again at step 2.
Adjustment 3

RF LEVEL DETECTOR OFFSET
  • Service Sheet 4

Description
With no RF input, the output from the RF level detector is adjusted for 0 Vdc while monitoring it with the internal voltmeter.

Procedure
1. Remove any cable from the Modulation Analyzer's INPUT.
2. Press RF POWER.
3. Key in 0.024 SPCL to switch out the 5.25 MHz high-pass filter and to set the RF Level Detector to normal output. Then, key in 49.31 SPCL to display the RF level with respect to RF ground. These steps set the input for an RF level measurement and connect the internal voltmeter to the RF detector output.
4. Adjust A15R42 (DET OFS) for a display between −0.001 and 0.001.
Adjustment 4

SAMPLER EFFICIENCY AND OFFSET
• Service Sheet 18

Description

Using the track-tune mode, the two signals into the sampler are configured so that the low-frequency VCXO is at a set frequency and the high-frequency VCO tracks the RF input signal. The output of the sampler is observed on an oscilloscope. The RF input is tuned to locate a zero-beat frequency at the sampler output then tuned for a 1 MHz beat. The sampler offset and efficiency (or frequency response) are then adjusted so that the dc offset is 50 mV and the amplitude of the 1 MHz waveform is the same as the zero beat.

NOTE

Improper adjustment of efficiency may result in the loop easily breaking or not attaining phase lock.

Equipment

Oscilloscope ................................................................. HP 1740A
Signal Source .............................................................. HP 8640B or HP 3336C

![Diagram of equipment setup]

Figure 5-2. Sampler Efficiency and Offset Adjustment Test Setup

Procedure

1. Set the signal source to 18 MHz CW at 0 dBm.

2. Connect the equipment as shown in Figure 5-2. (The oscilloscope input should be ac coupled. The signal source can be connected either to a sensor module or directly to the Modulation Analyzer’s INPUT.)

3. Set the oscilloscope’s vertical sensitivity to 0.2 V/division and horizontal scale for 10 μs/division.

4. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press TRACK MODE. If the instrument fails to tune to the 18 MHz signal, key in 18 MHz then press TRACK MODE.
5. Fine tune the signal source up slowly until a zero beat signal appears on the oscilloscope. Then increase the signal source frequency by 1 kHz. Note the frequency of the signal source. Note the peak-to-peak amplitude on the oscilloscope.

   Signal Source Frequency: __________ MHz

   Waveform Amplitude: __________ mVpp

6. Tune the signal source up by 29.0 kHz. This tunes the high-frequency VCO up $32 \times 30$ kHz $\approx 1$ MHz since the LO frequency is the HF VCO frequency divided by 32 on this band.

7. Adjust A23R34 (OFS) such that when the input coupling of the oscilloscope is changed from ac to dc the waveform shifts upward 50 mV. Adjust A23R34 only when the input coupling is set to dc.

8. Adjust A23R54 (EFF) for the same peak-to-peak amplitude on the oscilloscope as noted in step 5. If the adjustment has not enough range:
   a. Set A23R54 fully ccw and repeat steps 5 to 7.
   b. The signal amplitude step 5. Should be greater than in step 8, with A23R54 adjusted fully ccw. If it is not, replace A23R55 by higher values of resistance as listed in the following table. If this still does not have enough effect, replace A23C45 with 2.7 pF (HP Part Number 0160-4619).
   c. Adjust A23R54 for the same amplitude as noted in step 5.

9. Repeat step 7.

10. Key in 54.0 SPCL to run the LO tuning test. The display should show 0.

Adjustment 5

LO DOUBLER OUTPUT POWER AND BALANCE
• Service Sheet 17

Description
The power from the LO is monitored with a power meter while the LO is stepped through its doubler band. The bias and coupling components are changed as necessary to obtain the required power output. The LO is then monitored on a spectrum analyzer as the LO is swept slowly over its doubler band. The doubler balance is adjusted for minimum $1/2$ and $3/2$ harmonics of the doubled frequency.

NOTE
Excessive subharmonics can cause the LO to tune to a wrong frequency when automatically tuning.

Equipment
Sensor Module ................................................................. HP 11722A
RF Spectrum Analyzer ....................................................... HP 8559A/182T

Procedure

NOTE
In the following procedure, a power meter and power sensor combination can be substituted for the sensor module. The Modulation Analyzer can then be left in the frequency measurement mode.

1. Connect the sensor module to the Modulation Analyzer’s SENSOR and INPUT connectors.
2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument.
3. Zero and calibrate the sensor module using the RF power calibrator in the Modulation Analyzer. Set LOG/LIN to read in dBm.
4. Connect the sensor module’s input directly to A19J3 (LO OUT), or for Option 003, the rear-panel LO OUTPUT connector.
5. On the Modulation Analyzer, press FREQ. Key in 650 MHz to set the LO to the bottom of its doubler band.
6. Step the LO frequency up in 50 000 kHz steps. (Key in 50 000 $\uparrow$ kHz for the first step, then $\uparrow$ kHz thereafter.) For each step, press FREQ to tune the LO, then press RF POWER and note the power reading. Do this until Error 20 or Error 15 is displayed. (The LO has reached the top of its range or the frequency is beyond the range of the calibration factors of the sensor module.) The power readings should be between $+1.4$ and $+3.0$ dBm. If the power readings are within range, continue with step 7. If the power readings are out of range, change the components on A19 according to the following guidelines.
   a. To increase the power throughout the entire doubler band, decrease the value of A19R63. (Use values within the range 38.1 to 110Ω.)
   b. To eliminate low-frequency roll-off, increase the value of A10C43. Do not use a value of C48 that is larger than necessary or the effectiveness of the high-pass filter is reduced. (Use values within the range 4.7 to 15 pF.)
c. To eliminate high-frequency roll-off, increase the values of both A19R72 and R74 equally. (Use values within the range 121 to 619Ω.)

d. The effect of changing these components is interactive, therefore, whenever a component is changed, the power must be rechecked over the entire doubler band.

7. Set the spectrum analyzer to view a +10 dBm signal with a 0 to 2 GHz span width and log display. Connect its RF input to A19J3 (LO OUT), or for Option 003, the rear-panel LO OUTPUT connector.

8. On the Modulation Analyzer, press the blue key then press INSTR PRESET. Key in 55.0 SPCL to cause the LO to sweep slowly over its doubler range.

9. Adjust A19R41 (DBLR BAL) for the minimum level of the 1/2 and 3/2 harmonics of the doubled signal over the swept range. The 1/2 and 3/2 harmonics should be more than 30 dB below the doubled signal. The doubled signal sweeps from approximately 600 to 1300 MHz with a level of approximately +2 dBm.

**NOTE**

*To ease adjustment, note the frequency of the fundamental where harmonics are worst, manually tune to that frequency (use the frequency increment keys to assist in fine tuning), make the adjustment, then key in 55.0 SPCL and recheck the entire range. The sweep can be halted at any time by pressing the SPCL key.*
Adjustment 6

VOLTMETER OFFSET AND SENSITIVITY
- Service Sheets 14 and 15

Description

The dc offsets of the audio peak and average detectors are first adjusted. The voltmeter sensitivity is then adjusted while comparing the displayed reading to the level read by an external dc voltmeter. The sensitivity of the average detector is adjusted while comparing the average mode to the peak mode when detecting a sinusoidal signal.

Equipment

Audio Oscillator .......................................................... HP 8903B
Digital Voltmeter .......................................................... HP 3455A

![Diagram of Adjustment 6](image)

*Figure 5–3. Voltmeter Offset and Sensitivity Adjustment Test Setup*

Procedure

1. Connect the equipment as shown in Figure 5–3. Do not connect the audio oscillator to the Modulation Analyzer at this time. (The Modulation Analyzer’s INPUT can be connected either directly to the CALIBRATION RF POWER OUTPUT or through a sensor module.)

2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 45.16 SPCL to turn on the RF power calibrator. (This provides a signal for the Modulation Analyzer to tune to.)

3. On the Modulation Analyzer, set HP FILTER to 300 Hz and LP FILTER to 3 kHz. Key in 2.3 SPCL to set the audio gain to minimum. Key in 0.110 SPCL to set the audio input and audio overvoltage detector to no input and no reset. Key in 49. S (shift) 0 SPCL to set the voltmeter to measure and display the audio peak detector output.

4. Adjust A5R38 (PK DET OFS) for a display between 0.0003 and 0.0007.

5. Key in 49.9 SPCL to set the voltmeter to measure and display the average detector output.

6. Set A5R2 (RECT OFS) fully ccw to shut off A5U3.

7. Adjust A5R18 (AVG OFS) for a display between –0.0001 and +0.0001.
8. Set A5R2 (RECT OFS) fully cw then slowly ccw until the display reads between 0.0004 and 0.0006.

9. Set the audio oscillator for 2 kHz at 1 Vrms. Connect its output to A2J2 (FM IN) of the Modulation Analyzer as shown in Figure 5-3.

10. On the Modulation Analyzer, press FM. Key in 49.0 S (shift) 0 SPCL to connect the output from the audio peak detector to the RECORDER OUTPUT.

11. Adjust the audio oscillator level until the external voltmeter reads between +1.999 and +2.001 Vdc.

12. Adjust A5R73 (VM SENS) for a display on the Modulation Analyzer between 199.9 and 200.1, or if the level has drifted slightly, until the four digits of the display agree with the first four digits of the voltmeter reading to within ±1 digit.

14. Adjust A5R23 (AVG SENS) for a display on the Modulation Analyzer between 141.3 and 141.5, or if the level has drifted slightly, until the four digits of the display equals the voltmeter reading to within ±1 digit.

15. On the Modulation Analyzer, press PEAK+. Note the display. Press PEAK−. The two readings of the display should agree to within ±1 digit.

Adjustment 7

15 KHZ AND >20 KHZ LOW-PASS FILTER GAIN
• Service Sheet 12

Description

A signal generator is amplitude modulated at a 1 kHz rate. The signal is demodulated by the Modulation Analyzer with no low-pass, audio filtering. Using the ratio feature, the demodulated signal is referenced to 100%. The low-pass filtering is then set to >20 kHz and 15 kHz, then the filter gain of each is adjusted for a reading of 100%.

Equipment

Signal Generator ................................................................. HP 8640B

Procedure

1. Set the signal generator to 11 MHz at 0 dBm with 30% AM at a 1 kHz rate. Connect its RF output to the Modulation Analyzer's INPUT. (The signal source can be connected either to a sensor module or directly to the Modulation Analyzer's INPUT.)

2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Press AM. Set DETECTOR to AVG.

3. Set RATIO on (with LOG/LIN set for a linear display). The display should show between 99.95 and 100.05% REL.

4. Set LP FILTER to >20 kHz. Adjust A2R44 (>20 kHz LPF GAIN) for a display of 99.95 to 100.05% REL.

5. Set LP FILTER to 15 kHz. Adjust A2R40 (15 kHz LPF GAIN) for a display of 99.95 to 100.05% REL.
Adjustment 8

ALC REFERENCE
- Service Sheet 8

Description
The ALC reference voltage is adjusted while monitoring it with the internal voltmeter.

Procedure
1. Connect the CALIBRATION RF POWER OUTPUT to the INPUT. (The CALIBRATION RF
   POWER OUTPUT can be connected either to a sensor module or directly to the Modulation
   Analyzer’s INPUT.)

2. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset
   the instrument. Key in 45.16 SPCL to turn on the RF power calibrator. (This provides a signal
   for the Modulation Analyzer’s input.) Key in 49. S (Shift) 1 SPCL to connect the internal
   voltmeter to a node which represents the average IF level which the ALC loop forces to equal the
   ALC reference.

3. Adjust A6R65 (ALC REF) for a display between 2.0970 to 2.1030.
Adjustment 9—FM Calibrator

REFERENCE
Service Sheet 29.

DESCRIPTION
The FM calibrator is set to CW and its frequency is adjusted while being monitored by the internal counter. The calibrator is then set to modulate, and the symmetry is adjusted as the demodulated signal is measured with the peak+ and peak− detectors. The computed peak deviation is checked and if out of limits, a resistor is changed to bring the deviation within the proper limits.

NOTE
This calibration adjustment is not critical. Built-in safeguards minimize the possibility of erroneous calibration. If conditions exist that are out of calibration, the Measuring Receiver displays an error message.

PROCEDURE
1. Connect CALIBRATION AM/FM OUTPUT to INPUT. (The CALIBRATION AM/FM OUTPUT can be connected either to a sensor module or directly to the Measuring Receiver's INPUT.)
2. Key 12.1 SPCL and 46.3 SPCL. This sets the FM calibrator to CW and connects the internal counter to measure the calibrator's frequency.
3. Using a non-metallic tool, adjust A51C20 (FREQ) for a display between 1009000 and 1011000. If the frequency cannot be adjusted high enough, change A51R32 to 11 kΩ (HP part number 0757-0443).
4. Key in 12.2 SPCL then 5.1 SPCL. This sets the instrument to display the demodulated FM from the calibrator and sets the peak detector time constant to slow.
5. Alternately set the DETECTOR to PEAK+ and PEAK− and note the display for each setting. Adjust A51R12 (TRAPEZOID SYMM) until the readings are the same for both detectors within ±0.010 kHz.
6. Key in 12.0 SPCL to set the instrument to display the computed FM deviation from the FM calibrator. The display should read between 30 and 38 kHz. If the peak deviation exceeds these limits, alter the value of A51R24. Increasing the value of A51R24 by 10% will decrease the peak deviation by approximately 2.5 kHz. Use resistors indicated in the following table.

Adjustment 10

FM SENSITIVITY
- Service Sheet 11

Description
The FM sensitivity is adjusted for a calibration factor of 100% while the Modulation Analyzer measures the output of its FM calibrator.

Procedure
1. Perform Adjustment 9 — FM Calibrator.
2. Connect the CALIBRATION AM/FM OUTPUT to the INPUT. (The CALIBRATION AM/FM OUTPUT can be connected either to a sensor module or directly to the Modulation Analyzer's INPUT.)

NOTE
For best accuracy, allow the Modulation Analyzer to warm up for at least one-half hour.

3. Press FM then CALIBRATE. Allow at least two readings (approximately 40 seconds) to pass, then adjust A4R50 (FM SENS) for a display of 99.95 to 100.05%.
Adjustment 11

FM FLATNESS

- Service Sheet 11

Description
The AM/FM test source is frequency modulated at a 1 kHz rate with 400 kHz peak deviation. The demodulated FM is used as a reference. The modulation rate is increased to 150 kHz and the FM flatness is adjusted to bring the display back to the reference. The AM/FM test source is required to assure that the FM source has adequate bandwidth.

Equipment
AM/FM Test Source .......................................................... HP 11715A
Audio Synthesizer ........................................................... HP 3336C

![Figure 5-4. FM Flatness Adjustment Test Setup](image)

Procedure

1. Connect the equipment as shown in Figure 5-4 using a short cable, approximately 0.3 meters (1 foot), to connect the audio synthesizer. (The AM/FM test source can be connected either to a sensor module or directly to the Modulation Analyzer’s INPUT.)

2. With the leveling on, set the audio synthesizer to 1 kHz at +5 dBm. On the AM/FM test source, set the test mode to FM.

3. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument.

4. Tune the AM/FM test source’s carrier frequency to approximately 400 MHz.

5. On the Modulation Analyzer, press MHz to center its tuning. Press FM. Set DETECTOR to AVG. Adjust the audio synthesizer level for a display of approximately 280 kHz average deviation. Set RATIO on (with LOG/LIN set for a linear display).

6. Set the audio synthesizer frequency to 150 kHz without changing the level. Adjust A4R85 (FM FLATNESS) for a reading of 99.9 to 100.1% REL on the Modulation Analyzer.

NOTE

*If flatness does not adjust properly, try performing Adjustment 12 — FM Distortion and Incidental AM — 1.5 MHz IF.*
Adjustment 12

FM DISTORTION AND INCIDENTAL AM — 1.5 MHZ IF

* Service Sheet 5

Description

The AM/FM test source is frequency modulated at a 100 kHz rate with 400 kHz peak deviation. The peak deviation is measured with both the positive and negative peak detectors when the Modulation Analyzer is tuned first to the signal and then to its image. The IF is adjusted so that the difference between the detector readings is the same for both signals. This method permits proper adjustment of distortion even in the presence of a small amount of distortion from the FM source. The incidental AM is measured on an FM signal modulated at a 1 kHz rate and 50 kHz peak deviation. The instrument is adjusted for minimum AM.

Equipment

AM/FM Test Source ................................................................. HP 11715A
Audio Analyzer ................................................................. HP 8903B

![Diagram](image)

*Figure 5–5. FM Distortion and Incidental AM — 1.5 MHz Adjustment IF Test Setup*

Procedure

1. Connect the equipment as shown in Figure 5–5. (The AM/FM test source output can be connected either to a sensor module or directly to the Modulation Analyzer's INPUT.)

2. Set the audio analyzer's oscillator to 100 kHz at 4V. On the AM/FM test source, set the test mode to FM.

3. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Set the HP FILTER to 50 Hz.

4. Tune the AM/FM test source's carrier frequency to approximately 400 MHz.

5. On the Modulation Analyzer, press MHz to center its tuning. Press FM. Adjust the audio analyzer's oscillator level for a display of 400 kHz peak deviation on the Modulation Analyzer.

6. On the Modulation Analyzer, switch the DETECTOR between PEAK+ and PEAK− and note the difference between the two readings. Adjust A18R23 (FM DISTN 1.5 MHZ IF) for equal readings between PEAK+ and PEAK−.
7. On the Modulation Analyzer, key in 3000 kHz to tune the Modulation Analyzer to the signal image. Again switch between PEAK+ and PEAK−. The difference between the two readings should be less than 1.6 kHz. If it is not, adjust A18R23 again to diminish the difference by one half. Now note the reading for PEAK+ (PK1+) and PEAK− (PK1−). Press + kHz. Note the reading for PEAK+ (PK2+) and PEAK− (PK2−). The instrument is adjusted properly when:

\[|PK1+ + PK1− + PK2−| < 1.6 \text{ kHz.}\]

(Ideally, PK1+ should equal PK2−, and PK1− should equal PK2+.)

8. Connect the FM+4 output of the AM/FM test source to the Modulation Analyzer’s INPUT.

9. On the Modulation Analyzer, set LP FILTER to 3 kHz. Press AUTOMATIC OPERATION.

10. Set the audio analyzer’s oscillator frequency to 1 kHz and level for a display of 50 kHz deviation on the Modulation Analyzer.

11. On the Modulation Analyzer, press AM. Adjust A18R19 (INC AM 1.5 MHZ IF) for a minimum display (but less than 0.2%).

**NOTE**

The specification for incidental AM requires that 0.5 times the residual AM be subtracted out. The residual FM can be measured by momentarily disconnecting the audio input to the AM/FM test source and noting the displayed AM. Subtracting 0.5 times the displayed AM from the AM measurement in step 11 gives the actual incidental AM.
Adjustment 13

ΦM SENSITIVITY

- Service Sheet 13

Description

The AM/FM test source is frequency modulated with a sinusoidal signal at a 1 kHz rate and with 100 kHz peak deviation. This is equivalent to 100 rad peak deviation since

\[
\text{phase deviation} = \frac{\text{frequency deviation}}{\text{modulation rate}}.
\]

The ΦM sensitivity is adjusted for a reading of 100 rad.

Equipment

AM/FM Test Source ................................................................. HP 11715A
Audio Synthesizer................................................................. HP 3336C

![Diagram of equipment setup](image)

*Figure 5-6. ΦM Sensitivity Adjustment Test Setup*

Procedure

1. Connect the equipment as shown in Figure 5-6. (The AM/FM test source output can be connected either to a sensor module or directly to the Modulation Analyzer’s INPUT.)

2. Set the audio synthesizer to 1 kHz at +4 dBm. On the AM/FM test source, set the test mode to FM.

3. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Set HP FILTER to 300 Hz and LP FILTER to 3 kHz.

4. Tune the AM/FM test source’s carrier frequency to approximately 100 MHz.

5. On the Modulation Analyzer, press the MHz key to center its tuning. Press FM. Adjust the audio synthesizer for a display of 100 kHz on the Modulation Analyzer.
6. On the Modulation Analyzer, press \( \Phi \)M. Adjust A3R27 (\( \Phi \)M SENS) for a display of the same numerical value as the display in kHz of step 5 \( \pm 0.2 \) rad.

**NOTE**

*If a test oscillator is used in place of the audio synthesizer, the modulation rate must be measured with a counter (or simply key in \( S \) (Shift) AUDIO FREQ). The adjustment is then made to give a display equal to the ratio (frequency deviation)/(modulation rate).*
Adjustment 14

AM CALIBRATOR
* Service Sheet 30

Description
The Modulation Analyzer is set to read %AM as computed from internal measurements. The AM depth is adjusted for 33.33%. The AM is then demodulated and the symmetry is adjusted as the signal is measured with the peak+ and peak− detectors.

NOTE
This calibration adjustment is not critical. Built-in safeguards minimize the possibility of erroneous calibration. If conditions exist that are out of calibration, the Modulation Analyzer displays an error message.

Procedure
1. Connect CALIBRATION AM/FM OUTPUT to INPUT. (The CALIBRATION AM/FM OUTPUT can be connected either to a sensor module or directly to the Modulation Analyzer’s INPUT.)

2. Key in 13.0 SPCL. This sets the instrument to display the AM computed from internal measurements.

3. Adjust A50R45 ("A" LVL) for a display of 33.330 to 33.336%.

4. Key in 49.5 SPCL. This connects the internal voltmeter to measure the output level from the AM calibrator. The display should read between 1.8 and 2.2.

5. Key in 13.2 SPCL then 5.1 SPCL. This sets the instrument to display the demodulated AM from the calibrator and sets the peak detector time constant to slow.

6. Alternately set the DETECTOR to PEAK+ and PEAK− and note the display for each setting. Adjust A50R39 (SYMM) until the readings are the same for both detectors within ±0.015%.
Adjustment 15

AM SENSITIVITY

- Service Sheet 12

Description

The AM sensitivity is adjusted for a calibration factor of 100% while the Modulation Analyzer measures the output of its AM calibrator.

Procedure

1. Perform Adjustment 14 — AM Calibrator.

2. Connect the CALIBRATION AM/FM OUTPUT to the INPUT. (The CALIBRATION AM/FM OUTPUT can be connected either to a sensor module or directly to the Modulation Analyzer’s INPUT.)

   NOTE

   For best accuracy, allow the Modulation Analyzer to warm up for at least one-half hour.

3. Press AM then CALIBRATE. Allow at least two readings (approximately 40 seconds) to pass, then adjust A2R6 (AM SENS) for a display of 99.95 to 100.05%.
Adjustment 16

FM DISTORTION AND INCIDENTAL AM — 455 KHZ IF

- Service Sheets 5 and 8

Description

The signal generator is set to 2.45 MHz and frequency modulated at a 1 kHz rate with 10 kHz peak deviation. The incidental AM on the signal is measured and the instrument is adjusted for minimum AM. At 2.45 MHz the signal is not down converted by the Modulation Analyzer but goes directly into the IF. The adjustment alters the rolloff characteristic of a 2.5 MHz IF low-pass filter, which is the principal source of the incidental AM.

For the 455 kHz IF, the AM/FM test source is frequency modulated at a 10 kHz rate with 10 kHz peak deviation. The demodulated FM is measured with a distortion analyzer and FM distortion is adjusted for a minimum. The incidental AM is measured with FM set for a 1 kHz rate and 5 kHz peak deviation. The instrument is adjusted for minimum AM.

Equipment

AM/FM Test Source .......................................................... HP 11715A
Audio Analyzer ............................................................. HP 8901B
Signal Generator ............................................................ HP 8640B

![Diagram of equipment setup]

Figure 5–7. FM Distortion and Incidental AM — 455 kHz IF Adjustment Test Setup

Procedure

NOTE

In the following procedure the RF modulation source can be connected either to a sensor module (which is connected to the Modulation Analyzer) or directly to the Modulation Analyzer's INPUT connector. The procedure is written for the latter case.

1. Set the signal generator to 2.45 MHz at 0 dBm with 10 kHz peak FM deviation at a 1 kHz rate. Connect its RF output to the Modulation Analyzer's INPUT as shown in Figure 5–7.

2. On the Modulation Analyzer, press the blue key and then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 34.0 SPCL to measure the IF frequency. The IF should be approximately 2.45 MHz. If it reads approximately 0.455 MHz, tune the frequency down slightly until a reading of 2.45 MHz is obtained.

Adjustment 16 5–25
3. On the Modulation Analyzer, press AM. Set HP FILTER to 50 Hz, LP FILTER to 3 kHz, and DETECTOR to AVG. Adjust A6C8 (IF FLATNESS) for a minimum display (but less than 0.2%).

4. Disconnect the signal generator and connect the remaining equipment as shown in Figure 5-7.

5. Set the audio analyzer’s oscillator to 10 kHz at 4V. On the AM/FM test source, set the test mode to FM.

6. On the Modulation Analyzer, press FREQ. Tune the AM/FM test source’s carrier frequency to approximately 12.5 MHz.

7. On the Modulation Analyzer, key in 31 SPCL to set the IF to 455 kHz, press FM, and set LP FILTER to >20 kHz and DETECTOR to PEAK+.

8. Adjust the audio analyzer’s oscillator level for a Modulation Analyzer display of 10 kHz peak deviation.

9. Set the distortion analyzer (in the audio analyzer) to measure the distortion on the 10 kHz signal at the MODULATION OUTPUT/AUDIO INPUT with 30 kHz of low-pass filtering on the distortion analyzer.

10. Adjust A17L11 (FM DISTN 455 KHZ IF) for minimum distortion but less than 0.1% (less than –60 dB).

11. On the Modulation Analyzer, set LP FILTER to 3 kHz.

12. Set the audio analyzer’s oscillator frequency to 1 kHz and level for 5 kHz peak deviation on the Modulation Analyzer.

13. On the Modulation Analyzer, press AM. Adjust A17L8 (INC AM 455 KHZ IF) for a minimum display (but less than 0.2%).

**NOTE**

The specification for incidental AM requires that 0.5 times the residual AM be subtracted out. The residual AM can be measured by momentarily disconnecting the audio input to the AM/FM test source and noting the displayed AM on the Modulation Analyzer. Subtracting 0.5 times the displayed AM from the AM measured in step 14 gives the actual incidental AM.

14. If a significant adjustment was made in either step 10 or step 13, repeat steps 5 through 14.
Adjustment 17

TRACK-TUNE MODE OFFSET
- Service Sheet 20

Description

The Modulation Analyzer is tuned to a signal and put in the track-tune mode. The frequency of the IF is measured and the offset is adjusted to bring the frequency to within ±20 kHz of 1.5 MHz.

Procedure

1. Connect the CALIBRATION RF POWER OUTPUT to the INPUT. (The CALIBRATION RF POWER OUTPUT can be connected either to a sensor module or directly to the Modulation Analyzer's INPUT.)

2. Press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 45.16 SPCL to turn on the RF power calibrator. (This provides a signal for the Modulation Analyzer's input.)

3. Key in 34.0 SPCL to set the instrument to measure the IF frequency. Press TRACK MODE.

4. Adjust A20R1 (TRK OFS) for a display between 1.480 and 1.520 MHz.
Adjustment 18

POWER REFERENCE (USING REFERENCE COMPARISON)
- Service Sheet 3

Description

The frequency of the internal power reference is checked and adjusted, if necessary, to 50 MHz. The power from an external 1 mW power reference is measured with a power sensor and the power meter of the Modulation Analyzer. The same power sensor and power meter are then used to measure the power from the Modulation Analyzer's power reference. The Modulation Analyzer's power reference is adjusted to give the same reading as for the external power reference.

NOTE

After adjustment, the accuracy of the Modulation Analyzer's power reference will be ±1.2%. Greater accuracy can be obtained by using a recently calibrated external power reference or by following the procedure in Adjustment 19 — Power Reference (Using DC Substitution).

Equipment

Power Reference ................................................................. HP 435A Opt K05
Sensor Module ................................................................. HP 11722A

Procedure

1. Connect the sensor module’s cables to the SENSOR and INPUT of the Modulation Analyzer. Connect the sensor module’s input to the CALIBRATION RF POWER OUTPUT. (If a sensor module is not available, connect the Modulation Analyzer’s INPUT directly to the CALIBRATION RF POWER OUTPUT.)

2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 45.16 SPCL to turn on the RF power calibrator. Press TRACK MODE. The Modulation Analyzer’s display should read between 49.5 and 50.5 MHz.

3. If the frequency of the RF power calibrator is not within the proper limits, remove the thumb screw retaining the A32 Power Reference Oscillator and slide the assembly out. Adjust A32L1 for a frequency reading between 49.5 and 50.5 MHz. (The adjustment is accessed through a hole on the back side of the assembly.)

CAUTION

After removing the RF power calibrator assembly, take care that the power supply terminals do not short against the metal chassis parts.
NOTE

*If the frequency of the power reference is already within the proper limits, do not attempt to adjust the frequency to exactly 50 MHz. To do so may unnecessarily affect the level.*

4. Reinstall the A32 assembly. (The thumb screw need only be finger tight.)

5. Connect the input of the sensor module (or a compatible power sensor connected to the Modulation Analyzer's SENSOR input) to the output of the external power reference.

6. On the Modulation Analyzer, press ZERO and wait for the power sensor to zero.

7. On the Modulation Analyzer, press RF POWER. Press RATIO and check that LOG/LIN is in the linear mode. (The display should read between 99.9 and 100.1% REL.)

8. Connect the sensor module to the CALIBRATION RF POWER OUTPUT of the Modulation Analyzer. Press ZERO and allow the instrument to zero. Adjust A32R4 (LEVEL ADJ) for a reading between 99.9 and 100.1% REL. If the adjustment runs out of range, replace A32R5 with 7500Ω and readjust A32R4.
**Adjustment 19**

**POWER REFERENCE (USING DC SUBSTITUTION)**
- Service Sheet 3

**Description**

The frequency of the internal power reference is checked and adjusted, if necessary, to 50 MHz. The power from the power reference oscillator is measured by a method known as dc substitution. In this method a power-sensing thermistor is placed in one arm of a self-balancing, dc resistance bridge. With no power applied, the dc voltage supplying the top of the bridge is automatically adjusted until the thermistor heats to the temperature that produces the resistance required to bring the bridge into balance. When RF power is applied to the thermistor, the thermistor heats up and momentarily unbalances the bridge. The self-balancing circuits then readjust the supply voltage to the bridge to re-balance it. A second bridge, which senses only the ambient temperature, is employed to compensate for measurement drift. Careful measurement of the bridge dc voltages provides a way to determine the amount of RF power applied to the thermistor to a higher degree of accuracy than can be obtained by direct reading of the power meter.

**NOTE**

*After adjustment, the accuracy of the Modulation Analyzer's power reference will be ±0.7%. A simpler, but less accurate method for adjusting the power reference can be found in Adjustment 18 — Power Reference (Using Reference Comparison).*

**Equipment**

- Digital Voltmeter ................................................................. HP 3455A
- Power Meter ........................................................................ HP 432A
- Thermistor Mount ................................................................. HP 478A Opt H75

**Procedure**

1. On the Modulation Analyzer, connect the CALIBRATION RF POWER OUTPUT to the INPUT. (If a sensor module is being used, connect its input to the CALIBRATION RF POWER OUTPUT.)

2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 45.16 SPCL to turn on the RF power calibrator. Press TRACK MODE. The Modulation Analyzer's display should read between 49.5 and 50.5 MHz.

3. If the frequency of the RF power calibrator is not within the proper limits, remove the thumb screw retaining the A32 Power Reference Oscillator and slide the assembly out. Adjust A32L1 for a frequency reading between 49.5 and 50.5 MHz. (The adjustment is accessed through a hole on the back side of the assembly.)

**CAUTION**

*After removing the RF power calibrator assembly, take care that the power supply terminals do not short against the metal chassis parts.*
NOTE

If the frequency of the power reference is already within the proper limits, do not attempt to adjust the frequency to exactly 50 MHz. To do so may unnecessarily affect the level.

4. Reinstall the A32 assembly. (The thumb screw need only be finger tight.)

5. With the HP 432A Power Meter switched off and the thermistor interconnect cable connected to it but not to the thermistor mount, measure the resistance between the center conductor of the rear-panel VRF connector and pin 1 (the first pin to the right of the key slot) on the thermistor end of the interconnect cable. Record the value of the mount resistance for future reference. (It should be approximately 200Ω.)

   Mount Resistance (R): _________________ Ω

6. Connect the equipment as shown in Figure 5–8. The input of the digital voltmeter should be floating. The positive input of the voltmeter should be connected to the rear-panel VCOMP connector of the HP 432A Power Meter, the negative input to the VRF connector. Switch the equipment on and let it warm up for at least 30 minutes.

![Figure 5–8. Power Reference Adjustment Test Setup](image)

7. On the Modulation Analyzer, key in 45.0 SPCL to switch the power reference off.

8. Set the HP 432A Power Meter RANGE to COARSE ZERO and adjust the front-panel COARSE ZERO to obtain a zero meter indication.

9. Fine zero the HP 432A Power Meter on the most sensitive range, then set the RANGE switch to 1 mW (0 dBm).

10. Observe the voltage reading on the voltmeter. If the reading is greater than 400 µV, press and hold the FINE ZERO switch on the HP 432A Power Meter and adjust COARSE ZERO so that the voltmeter reads less than 200 µV then release the FINE ZERO switch. Record the voltmeter reading.

   \[ V_{COMP} - V_{RF} \text{ with No Power (V₀): } \quad \text{Vdc} \]

11. Connect the voltmeter to read \( V_{COMP} \) (with respect to chassis ground) on the HP 432A Power Meter. (The voltmeter's negative input should connect to chassis ground.)

12. On the Modulation Analyzer, key in 45.16 SPCL. Record the voltmeter reading.

   \[ V_{COMP} \text{ with } 1 \text{ mW: } \quad \text{Vdc} \]

13. Reconnect the voltmeter leads as shown in Figure 5–8 (where VRF is connected to the negative input of the voltmeter).
14. The voltmeter is now set up to measure $V_1$, which represents the reference output level. Compute the desired value of $V_1$ (for 1 mW) from the equation

$$V_1 = V_{COMP} - \sqrt{(V_{COMP} - V_0)^2 - 0.004RH}$$

where $H$ is the effective efficiency of the thermistor mount at 50 MHz as read from the mount's label.

Desired $V_1$: __________ Vdc

15. Adjust A32R4 (LEVEL ADJ) until the voltmeter reading is the same as $V_1$ computed in step 14. If the adjustment runs out of range, replace A32R5 with 71000 and readjust A32R4.
Adjustment 20

POWER METER
- Service Sheet 1

Description
The frequency of the 220 Hz multivibrator is adjusted for a maximum power reading of a nominal input signal. This occurs when the phase shift through the ac amplifier chain of the power meter is zero. Two linearity adjustments are then made on the two highest power ranges using a power meter range calibrator.

Equipment
- Extender Cable
- Range Calibrator

Procedure
1. Connect the power meter output of the range calibrator to the Modulation Analyzer’s SENSOR input.
2. On the range calibrator, set the function to calibrate, polarity to normal, and range to 1 mW.
3. On the Modulation Analyzer, press RF POWER. Adjust A53R40 (FREQ) for a maximum reading on the Modulation Analyzer’s display (approximately 1 mW).
4. On the Modulation Analyzer, press S (Shift) AUDIO FREQ. Set AUDIO INPUT to read external.
5. On the Modulation Analyzer, connect the MODULATION OUTPUT/AUDIO INPUT to A53TP4 (MLTIVIB). The Modulation Analyzer’s display should read between 204 and 236 Hz.
6. Remove the cable from A53TP4.
7. On the range calibrator, set the function to standby.
9. On the range calibrator, set the function to calibrate.
10. On the Modulation Analyzer, press CALIBRATE then press the blue key then press SAVE CAL (again, the CALIBRATE key). This normalizes the power reading to 1 mW. (The CALIBRATE key light should be on.)
11. On the Modulation Analyzer, key in 10.4 SPCL to set the power meter to range 4.
12. Set the range calibrator range to 10 mW. The Modulation Analyzer’s display should read between 9.99 and 10.01 mW. If it does not, perform the following steps.
   a. Switch the Modulation Analyzer off and extend the A53 RF Power Assembly.
   b. Connect the extender cable to the RF Power Assembly. Connect the range calibrator to the sensor connector on the extender cable.
   c. Switch the Modulation Analyzer back on. Repeat steps 7 to 12.
   d. Adjust A53R13 (RNG 4) for a Modulation Analyzer display of 10.00 mW.
13. On the Modulation Analyzer, key in 10.5 SPCL to set the power meter to range 5.
14. Set the range calibrator range to 100 mW. The Modulation Analyzer's display should read between 99.9 and 100.1 mW. If it does not, perform the following steps.
   a. If the A53 RF Power Assembly is already extended, go to step e.
   b. Switch the Modulation Analyzer off and extend the A53 RF Power Assembly.
   c. Connect the extender cable to the RF Power Assembly. Connect the range calibrator to the sensor connector on the extender cable.
   d. Switch the Modulation Analyzer off and extend the A53 RF Power Assembly. (Reconnect the two cables on the top of the assembly.)
   e. Switch the Modulation Analyzer back on. Repeat steps 7 to 14.
   d. Adjust A53R16 (RNG 5) for a Modulation Analyzer display of 100.0 mW.
Adjustment 21

AUDIO TRUE RMS DETECTOR AND NOTCH FILTER GAIN

* Service Sheet 16

Description
The offset of the audio true rms detector is first adjusted to read zero with no audio input, then a signal of known level is applied to the detector and the sensitivity of the detector is adjusted to read the correct level. The gain of the audio notch filter is adjusted for a reading of 100% with an input signal that is twice the frequency of the notch filter.

Equipment
Audio Oscillator ................................................................. HP 8903B
Digital Voltmeter ............................................................... HP 3455A

![Diagram](image)

*Figure 5-9. Audio True RMS Detector and Notch Filter Gain Adjustment Test Setup*

Procedure
1. Remove any cable from the MODULATION OUTPUT/AUDIO INPUT connector of the Modulation Analyzer.
2. On the Modulation Analyzer, press the blue key then press INSTR PRESET (the AUTOMATIC OPERATION key) to preset the instrument. Key in 30.0 SPCL to set the instrument to measure and display the voltage at the MODULATION OUTPUT/AUDIO INPUT connector with the audio true rms detector. Key in 49.7 SPCL to measure and display the output of the audio true rms detector. (The displayed voltage will be ten times the level displayed with Special Function 30.)
3. Adjust A52R47 (RMS OFS) for a reading on the Modulation Analyzer's display between -0.0005 and 0.0005.
4. Key in 30.0 SPCL. The display should read 0.0000 V.
5. Connect the equipment as shown in Figure 5-9.
6. Set the audio oscillator for 3.9 Vrms into an open circuit at 2 kHz. Set the voltmeter to read ac volts.
7. Adjust A52R38 (RMS SENS) for a reading on the display of the Modulation Analyzer that is the same as the reading on the voltmeter to the third decimal place. (The readings should be approximately 3.9 Vrms.)
8. Set the audio oscillator level to 100 mVRms.

9. On the Modulation Analyzer, press S (Shift) AUDIO DISTN. Adjust A52R44 (NOTCH FLTR GAIN) for a display on the Modulation Analyzer between 99.9 and 100.1%.

10. Set the audio oscillator frequency to 800 Hz.

11. On the Modulation Analyzer, press the blue key then press 400 Hz DISTN (the PEAK- key). The Modulation Analyzer’s display should read greater than 98%.
Adjustment 22

BATTERY BACKUP
• Service Sheet 24

Description
The battery backup circuit switches the supply for the internal RAM to an internal battery when either the +12V or +5V supply drops. The two supplies are measured on the memory assembly and the voltage at which the backup switches is adjusted to a level based on the measured supply voltages.

Equipment
Digital Voltmeter ................................................................. HP 3455A

Procedure
1. Connect the voltmeter to A13TP10 (+5V). Measure and record the dc voltage with respect to ground.
   
   \[
   \text{Voltage at A13TP10} = \text{Vdc}
   \]

2. Connect the voltmeter to A13TP12 (+12V). Measure and record the dc voltage with respect to ground.
   
   \[
   \text{Voltage at A13TP12} = \text{Vdc}
   \]

3. Make the following calculations.
   
   \[
   \frac{2}{5} \times \text{Voltage at A13TP10} = \text{Vdc}
   \]

   \[
   \frac{1}{6} \times \text{Voltage at A13TP12} = \text{Vdc}
   \]

4. Make the following calculation.
   
   \[
   0.95 \times \text{Lowest Voltage of Step 3} = \text{Vdc}
   \]

5. Connect the voltmeter to A13TP11 (VR). Adjust A13R12 (VR) until the voltmeter reads within ±0.05V of the voltage calculated in step 4.

INDEX

% CAL FACTOR,
in AM measurements, 3-141
RF power calibration, 3-71

--
--
-- --, 3-166, 3-247, 3-250
-- -- --, 3-247

0.001 dB resolution, 3-246
0.1 Hz resolution, 3-246

1
1 mW power reference oscillator, 3-71
1 kHz DISTN, 3-201, 3-203
1.5 MHz IF frequency, 3-125
1.5 MHz IF detector, 3-229
10 MHz time base, 3-3

4
400 Hz DISTN, 3-201, 3-203
455 kHz IF detector, 3-229
455 kHz IF frequency, 3-125

5
50 MHz reference calibration factor, 3-71

7
750 us de-emphasis, 3-160

A
accounting for external attenuation, 3-105
accuracy, in RF power measurements, 3-71
adjacent-channel power measurements, 3-95, 3-96
agile frequency sources, measuring, 3-113, 3-119
AM, 3-135
affected by IF level, 3-93
ALC response time, 3-139
as dB down from the carrier, 3-218
calibration, 3-141
increasing accuracy of measurements, 3-137
OUTPUT, 3-137, 3-147
attenuation, external; compensating for, 3-105
attenuation, selecting, 3-231
audio detector, 3-173
response, 3-241
response time, 3-177
AUDIO DISTN, 3-201
audio filters, 3-179
AUDIO FREQUENCY, 3-199
AUDIO INPUT, 3-187, 3-199, 3-201
audio level measurements, 3-201
audio range selection, 3-241
audio range, 3-183
AUTO TUNING, 3-115
automatic cal factors, 3-71
automatic level control, 3-242
AUTOMATIC OPERATION, 3-207
automatic tuning, 3-115

C
CALIBRATE,
In AM measurements, 3-141
In FM measurements, 3-155
RF power calibration, 3-71
calibration factors, AM, 3-244
calibration factors, FM, 3-244
calibration factors, RF power, 3-71, 3-74, 3-246
Automatic, 3-71
equivalent HP-IB program for entering, 3-81
calibration, frequency-dependent, 3-71
Manual, 3-79, 3-80
resolution, 3-79
calibration, AM, 3-141, 3-243
FM, 3-155, 3-243
RF power, 3-71
cellular radio measurements, 3-95
channel accuracy, checking, 3-123
CLEAR, 3-26, 3-211
used with HP-IB, 3-18, 3-22
comparing frequencies, 3-115
compensating for external attenuation, 3-105

D
dB and frequency resolution, 3-246
dB EXT ATTEN, 3-105
de-emphasis, 3-159
DETECTOR, 3-173
detector response time, 3-177
DISABLE ERROR, 3-238
DISPLAY FREQUENCY, 3-115
DISPLAY FREQUENCY INCREMENT, 3-115
down converter, using the 8901 as, 3-103
down-converting a microwave signal, 3-225
drifting signals, measuring, 3-121

E
entering RF power calibration factors, 3-72
equivalent HP-IB program for entering, 3-81
Index

error 03, 3-231
error 04, 3-185, 3-234
error 05, 3-172
error 06, 3-86
error 07, 3-235
error 11, 3-217
error 17, 3-250
error 24, 3-14
error message disable control, 3-233, 3-242
error message summary, 3-247
external attenuation (dB), 3-105, 3-245
external audio rms level measurement, 3-246, 3-201
external LO, using an, 3-225
external LO, 3-245

F

filters, RF and IF, 3-229
filters, audio, 3-179
firmware date codes 234.1985 and below, 3-78, 3-131, 3-177, 3-200, 3-204, 3-218, 3-241, 3-242, 3-246,
flatness, measuring, 3-117
flatness, modulation; checking, 3-218
FM calibration, 3-155
FM DE-EMPHASIS, 3-159
FM OUTPUT, 3-163
FM, 3-151
FM, deviation relative to 75 kHz, 3-218
FREQ ERROR, 3-121
FREQ ERROR, parts per million display, 3-123
FREQ OFST TTL OUT, 3-226, 3-227
FREQ, 3-111
frequency agile sources, measuring, 3-113, 3-119
frequency dependent calibration factors in RF power, 3-71
frequency offset control, 3-225, 3-245
frequency resolution, 3-111
frequency tuning, 3-115
fuses, 3-2

G

gain, external; compensating for, 3-105

H

high-selectivity power measurements, 3-95
HP FILTER, 3-179
HP-IB address, 3-244

HP-IB,

801A/01B code differences, 3-45
8901 automatically selects pre-display, 3-174
abort, 3-32
address, 3-33
alpha characters, 3-13
ASCII characters not used, 3-14
capabilities, 3-19, 3-20, 3-21
CLEAR key, 3-21, 3-22
clear, 3-24, 3-209
code sequence, 3-16
codes, 3-37, 3-38
commas, 3-13
data output, 3-18
device clear, 3-24
every program for RF power cal factor entry, 3-81
example, 3-17
invalid characters, 3-14
local, 3-26
measurement example, 3-17
pass control, 3-32
peak hold cycles, 3-175
remote, 3-25
RF power calibration, 3-79
service request, 3-26
spaces, 3-13
SRQ mask, 3-29
SRQ, 3-26
status byte, 3-31
syntax, numeric, 3-16
syntax, programming, 3-15
take control, 3-32
trigger codes, 3-17
trigger, 3-21, 3-22
turning off functions, 3-14
using the tone-burst receiver, 3-166

I

IF filters, 3-229
IF frequency, 3-125, 3-246
IF LEVEL, 3-93
IF LEVEL, affects AM accuracy, 3-93
IF OUTPUT, 3-103
IF OUTPUT, used to check for spurious signals, 3-103
image frequencies, 3-118
impedance, source, 3-79
increment steps, 3-116, 3-117
input attenuation, 3-251
INPUT FREQ, 3-115
INSTR PRESET, 3-209
internal checks, 3-209
internal voltmeter; used to make measurements, 3-87

K

kHz, kHz, 3-115

L

level measurements, scaling, 3-105
limit, 3-219, 3-243
LO frequency, 3-127, 3-246
LO INPUT and LO OUTPUT, 3-129
local lockout, 3-25
LOG/LIN, 3-215
losing instrument states, 3-211
low-noise LO frequency tuning, 3-115
LP FILTER, 3-179

M
manual calibration factors for RF power, 3-79
manual tuning, 3-115
measurement codes used in limits, 3-220
MODULATION OUTPUT, 3-187
modulation range, 3-183
multi-channel transmitters, checking channel accuracy, 3-123
multiple signal sources, measuring, 3-113, 3-119

N
noise effects, residual, 3-191
noise measurements, single-sideband, 3-95
normalizing noise measurements, 3-95

O
offset in input attenuation, compensating for, 3-105
offsetting the LO, for selective power measurements, 3-95
option 003, 3-129
option 030, 3-95, 3-246,

P
parts per million display; frequency error measurements, 3-123
peak detectors,
in AM measurements, 3-137
in FM measurements, 3-154
phase lock, LO does not, 3-128
phase modulation, 3-169
in degrees, 3-172
recommended filter selection, 3-172
phase shift keying, 3-172
power measurements, RF, 3-71
power measurements, adjacent channel, 3-95
power sensor,
changing, 3-79
in RF power measurements, 3-71
user-built, 3-79, 3-107
power-up and default conditions, 3-209
pre-emphasis equalization, 3-159
PREVIOUS RATIO, 3-215, 3-243
program, example for entering RF power cal factors, 3-81
pull-out cards, 3-2
pulsed phase modulation, 3-172

R
RANGE HOLD, 3-213
range, audio, 3-183
range, modulation, 3-183
ratio measurements, common, 3-218
RATIO, 3-215, 3-219
recalibrating RF power, reasons, 3-78
RECALL, 3-223
RECAL,
in RF power measurements, 3-78
receiver, setting up the 8901 as, 3-235
recorder output, for RF power measurements, 3-87
remote control RF switch, 3-107
residual noise effects, 3-191
resolution, finer for audio frequency measurements, 3-200
resolution,
frequency, 3-131
RF power calibration factor, 3-79
RF and IP filters, 3-241
RF filters, 3-229
RF frequency error, 3-121
RF frequency resolution, 3-131, 3-242
RF frequency tuning, 3-115
RF input attenuation, 3-231, 3-241
RF input frequency, 3-111
RF level measurements, 3-85
RF power range, 3-243
RF POWER, 3-71
calibration, 3-71
reasons to recalibrate, 3-78
using the internal voltmeter with, 3-87
RF POWER, when initiates RF level measurements, 3-85
rms calibrated average as peak, 3-218
rms calibrated average as true average, 3-218
RMS, 3-201
RMS detector, considerations when using, 3-154
SAVE CAL,
in AM calibration, 3-141
in FM calibration, 3-155
RF power calibration, 3-71, 3-80
selective power measurements, 3-95, 3-245
selectivity, increasing, 3-229
sensitivity,
increasing, 3-229
sensor module,
in RF power measurements, 3-71
user-built, 3-79, 3-107
sensor, power, in RF power measurements, 3-71
service request, 3-26, 3-244
SINAD, 3-203, 3-245
single-sideband noise measurements, 3-95, 3-98
source impedance, 3-79
special display, 3-239
special, special display, 3-240
spurious signals, check for using the IF output, 3-103
squelch tone measurement, 3-165
squelching, automatic if the input signal drops, 3-154
SRQ, 3-26
status bit, 3-32
stepping frequency, 3-116, 3-117
STORE, 3-223
switch, remote control RF, 3-107

T

table of calibration factors, 3-71
table of calibration factors, storing, 3-79
time base, 3-3
tone-burst receiver, the 8901 as, 3-165
tone-burst receiver mode, 3-244
TRACK MODE, 3-115
TUNED RF LEVEL, 3-91
tuning, frequency, 3-115

U

user-built sensor module, 3-79, 3-107

V

voltmeter, internal; used to make measurements, 3-87

Z

ZERO, RF power calibration, 3-71
