OPERATING GUIDE for
SOLAR ARRAY SIMULATOR
AGILENT MODELS E4350B, E4351B

Agilent Model E4350B: US37410101 and Above *
Agilent Model E4351B: US37430101 and Above *

* For instruments with higher Serial Numbers, a change page may be included.
CERTIFICATION

Agilent Technologies Company certifies that this product met its published specifications at time of shipment from the factory. Agilent Technologies further certifies that its calibration measurements are traceable to the United States National Bureau of Standards, to the extent allowed by the Bureau's calibration facility, and to the calibration facilities of other International Standards Organization members.

WARRANTY

This Agilent Technologies hardware product is warranted against defects in material and workmanship for a period of three years from date of delivery. Agilent software and firmware products, which are designated by Agilent for use with a hardware product and when properly installed on that hardware product, are warranted not to fail to execute their programming instructions due to defects in material and workmanship for a period of 90 days from date of delivery. During the warranty period Agilent Technologies Company will, at its option, either repair or replace products which prove to be defective. Agilent does not warrant that the operation of the software, firmware, or hardware shall be uninterrupted or error free.

For warranty service, with the exception of warranty options, this product must be returned to a service facility designated by Agilent. Customer shall prepay shipping charges by (and shall pay all duty and taxes) for products returned to Agilent for warranty service. Except for products returned to Customer from another country, Agilent shall pay for return of products to Customer.

Warranty services outside the country of initial purchase are included in Agilent's product price, only if Customer pays Agilent international prices (defined as destination local currency price, or U.S. or Geneva Export price).

If Agilent is unable, within a reasonable time to repair or replace any product to condition as warranted, the Customer shall be entitled to a refund of the purchase price upon return of the product to Agilent.

LIMITATION OF WARRANTY

The foregoing warranty shall not apply to defects resulting from improper or inadequate maintenance by the Customer, Customer-supplied software or interfacing, unauthorized modification or misuse, operation outside of the environmental specifications for the product, or improper site preparation and maintenance. NO OTHER WARRANTY IS EXPRESSED OR IMPLIED. AGILENT SPECIFICALLY DISCLAIMS THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

EXCLUSIVE REMEDIES

THE REMEDIES PROVIDED HEREIN ARE THE CUSTOMER'S SOLE AND EXCLUSIVE REMEDIES. AGILENT SHALL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, WHETHER BASED ON CONTRACT, TORT, OR ANY OTHER LEGAL THEORY.

ASSISTANCE

The above statements apply only to the standard product warranty. Warranty options, extended support contracts, product maintenance agreements and customer assistance agreements are also available. Contact your nearest Agilent Technologies Sales and Service office for further information on Agilent's full line of Support Programs.
SAFETY SUMMARY

The following general safety precautions must be observed during all phases of operation, service, and repair of this instrument. Failure to comply with these precautions or with specific warnings elsewhere in this manual violates safety standards of design, manufacture, and intended use of the instrument. Agilent Technologies Company assumes no liability for the customer’s failure to comply with these requirements.

BEFORE APPLYING POWER.
Verify that the product is set to match the available line voltage and the correct fuse is installed.

GROUND THE INSTRUMENT.
This product is a Safety Class 1 instrument (provided with a protective earth terminal). To minimize shock hazard, the instrument chassis and cabinet must be connected to an electrical ground. The instrument must be connected to the ac power supply mains through a three-conductor power cable, with the third wire firmly connected to an electrical ground (safety ground) at the power outlet. For instruments designed to be hard-wired to the ac power lines (supply mains), connect the protective earth terminal to a protective conductor before any other connection is made. Any interruption of the protective (grounding) conductor or disconnection of the protective earth terminal will cause a potential shock hazard that could result in personal injury. If the instrument is to be energized via an external autotransformer for voltage reduction, be certain that the autotransformer common terminal is connected to the neutral (earthed pole) of the ac power lines (supply mains).

FUSES.
Only fuses with the required rated current, voltage, and specified type (normal blow, time delay, etc.) should be used. Do not use repaired fuses or short circuited fuseholders. To do so could cause a shock or fire hazard.

DO NOT OPERATE IN AN EXPLOSIVE ATMOSPHERE.
Do not operate the instrument in the presence of flammable gases or fumes.

KEEP AWAY FROM LIVE CIRCUITS.
Operating personnel must not remove instrument covers. Component replacement and internal adjustments must be made by qualified service personnel. Do not replace components with power cable connected. Under certain conditions, dangerous voltages may exist even with the power cable removed. To avoid injuries, always disconnect power, discharge circuits and remove external voltage sources before touching components.

DO NOT SERVICE OR ADJUST ALONE.
Do not attempt internal service or adjustment unless another person, capable of rendering first aid and resuscitation, is present.

DO NOT EXCEED INPUT RATINGS.
This instrument may be equipped with a line filter to reduce electromagnetic interference and must be connected to a properly grounded receptacle to minimize electric shock hazard. Operation at line voltages or frequencies in excess of those stated on the data plate may cause leakage currents in excess of 5.0 mA peak.

SAFETY SYMBOLS.

⚠️ Instruction manual symbol: the product will be marked with this symbol when it is necessary for the user to refer to the instruction manual (refer to Table of Contents).

📈 Indicates hazardous voltages.

☒ or ☐ Indicate earth (ground) terminal.

WARNING The WARNING sign denotes a hazard. It calls attention to a procedure, practice, or the like, which, if not correctly performed or adhered to, could result in personal injury. Do not proceed beyond a WARNING sign until the indicated conditions are fully understood and met.

CAUTION The CAUTION sign denotes a hazard. It calls attention to an operating procedure, or the like, which, if not correctly performed or adhered to, could result in damage to or destruction of part or all of the product. Do not proceed beyond a CAUTION sign until the indicated conditions are fully understood and met.

DO NOT SUBSTITUTE PARTS OR MODIFY INSTRUMENT.
Because of the danger of introducing additional hazards, do not install substitute parts or perform any unauthorized modification to the instrument. Return the instrument to an Agilent Technologies Sales and Service Office for service and repair to ensure that safety features are maintained.

Instruments which appear damaged or defective should be made inoperative and secured against unintended operation until they can be repaired by qualified service personnel.
SAFETY SUMMARY (continued)

GENERAL
Any LEDs used in this product are Class 1 LEDs as per IEC 825-1.

ENVIRONMENTAL CONDITIONS

All instruments are intended for indoor use in an installation category II, pollution degree 2 environment. They are designed to operate at a maximum relative humidity of 95% and at altitudes of up to 2000 meters. Refer to the specifications tables for the ac mains voltage requirements and ambient operating temperature range.

Manufacturer’s Declaration

This statement is provided to comply with the requirements of the German Sound Emission Directive, from 18 January 1991.

* Sound Pressure Lp <70 dB(A) * At Operator Position * Normal Operation * According to EN 27779 (Type Test).
DECLARATION OF CONFORMITY
according to ISO/IEC Guide 22 and EN 45014

Manufacturer's Name: Agilent Technologies Company

Manufacturer's Address: 150 Green Pond Road
Rockaway, New Jersey 07866
U.S.A.

declares that the Product

Product Name: Solar Array Simulator
Model Number: Agilent E4350A, E4350B, E4351B

conforms to the following Product Specifications:

EMC: CISPR 11:1990 / EN 55011:1991 - Group 1 Class A
IEC 801-2:1991 / EN 50082-1:1992 - 4 kV CD, 8 kV AD
IEC 801-3:1984 / EN 50082-1:1992 - 3 V / m
IEC 801-4:1988 / EN 50082-1:1992 - 0.5 kV Signal Lines
1 kV Power Lines

Supplementary Information:

The product herewith complies with the requirements of the Low Voltage Directive

PRINTING HISTORY
The edition and current revision of this manual are indicated below. Reprints of this manual containing minor corrections
and updates may have the same printing date. Revised editions are identified by a new printing date. A revised edition
incorporates all new or corrected material since the previous printing date. Changes to the manual occurring between
revisions are covered by change sheets shipped with the manual. In some cases, the manual change applies only to specific
instruments. Instructions provided on the change sheet will indicate if a particular change applies only to certain
instruments.

General Information

What’s In This Guide?

This guide describes the Agilent Model E4350B/E4351B Solar Array Simulator (SAS). An overview of the unit is given in this chapter. Installation and user connections are discussed in chapters 2 and 4. Programming from the front panel and over the GPIB is discussed in chapters 5-7. If you just need to check that the unit is operating properly, read chapter 3.

The edition and current revision of this manual are indicated on the title page. Reprints of this manual containing minor corrections and updates may have the same printing date. Revised editions are identified by a new printing date. A revised edition incorporates all new or corrected material since the previous printing date.

Changes to the manual occurring between revisions are covered by change sheets shipped with the manual. In some cases, the manual change applies only to specific instruments. Instructions provided on the change sheet will indicate if a particular change applies only to certain instruments.

Safety Considerations

The Agilent Solar Array Simulator is a Safety Class 1 instrument, which means it has a protective earth terminal. That terminal must be connected to earth ground through a power source equipped with a 3-wire ground receptacle. Refer to the Safety Summary page at the beginning of this guide for general safety information. Before installation or operation, check the Agilent SAS and review this guide for safety warnings and instructions. Safety warnings for specific procedures are located at appropriate places in the guide.

### Description

The Agilent E4350B/E4351B Solar Array Simulator (SAS) is a dc power source that simulates the output characteristics of a solar array. The Agilent SAS is primarily a current source with very low output capacitance. It is capable of simulating the I-V curve of a solar array under different conditions such as temperature and age. The I-V curve is programmable over the IEEE-488.2 bus and is automatically generated within the Agilent SAS. The Agilent SAS has three operating modes:

**Fixed Mode:** This is the default mode that occurs when the unit is first powered up. The I-V output has the rectangular characteristics of a standard power supply, but with excellent high speed constant current characteristics and low output capacitance. Fixed mode allows front panel programming and is convenient when, in certain applications, the I-V curve is not needed.

**Simulator Mode:** An internal algorithm is used to simulate a SAS I-V curve. One can easily approximate the curve through four input parameters: open circuit voltage (Voc), short circuit current (Isc), current at the approximate maximum power point on the curve (Imp), and voltage at the approximate maximum power point on the curve (Vmp).

**Table Mode:** The Agilent SAS provides a table mode for a fast and accurate I-V simulation of solar arrays. In this mode, a table of I-V points, often provided by the solar array manufacturer, specifies the curve. The Agilent SAS provides up to 60 tables with a total of 33,500 I-V points of storage and a maximum of 4,000 I-V points per table. The tables (I-V curves) are easily stored and recalled. A portion of table storage is allocated in non-volatile memory, with 30 possible tables totaling 3,500 points. These are retained when power is turned off. In table mode, current and voltage offsets can be applied to the selected table to simulate a change in the operating conditions of the solar array.

### Key Features

- 480 Watt output
- Auto-parallel capability for higher power
- Very low output capacitance
- Switching recovery time in less than 5 microseconds
- Programmable overvoltage and over-current protection which are independent of other circuits
- Overtemperature protection
- Fan speed control to minimize acoustic noise
- Extensive set of programming features
- Fast I-V curve change in both table and simulator modes
- Up to 60 volatile/non-volatile tables
- Self test at power-up or from an IEEE-488.2 command
- Serial link to connect up to 16 outputs to one IEEE-488.2 address
- Standard Commands for Programmable Instruments (SCPI)
Output Characteristic

The Agilent E4350B/E4351B Solar Array Simulator can be operated in three modes: fixed mode, simulator mode, and table mode. Mode switching on the Agilent SAS is accomplished over the GPIB bus via the SCPI CURRent:MODE command. You cannot switch modes from the front panel.

Note: The Agilent SAS must be connected to a computer for you to be able to use the SAS functions that are available in simulator and table modes.

The front panel does not indicate which mode the Agilent SAS is presently operating in. If you are unsure which mode the unit is presently in, you can query the unit over the GPIB using the CURRent:MODE? command. If you cycle power to the unit, it will be in Fixed mode.

Fixed Mode

At power turn on, with *RST, or when executing a Device Clear, the operating state of the Agilent SAS is Fixed mode (see Figure 1-1). In Fixed mode, the output characteristic is similar to that of a standard power supply, except that the output capacitance is <100 nF on the Agilent E4350B, and <50 nF on the Agilent E4351B. This low output capacitance is ideal when using the unit as a constant current source. To use the unit as a low-impedance constant voltage source however, you can add an external output capacitor if so desired. The value of the external capacitor should not exceed 2,000 µF.

![Figure 1-1. Fixed Mode Characteristic](image)

Restrictions

- If the programmed values exceed the maximum current and voltage boundaries by more than 2 or 3 percent, an OUT OF RANGE error will be indicated.

Simulator Mode

Simulator mode uses an exponential model to approximate the I-V curve (see Figure 1-2). It is programmed in terms of its open circuit voltage (Voc), short circuit current (Isc), voltage point (Vmp), and current point (Imp) at approximately the peak power point (see page A-9 in appendix A for model equations). Simulator mode operation is achieved by sampling the output voltage, applying a low-pass filter, and continually adjusting the constant current loop by using the filtered voltage as an index into the exponential model.
Note that under certain conditions, such as if Imp is significantly less than Isc, the model equation will exhibit a certain degree of inaccuracy in that the actual maximum power point (Pmp) and value may be somewhat different from the expected value of Pmp (Imp x Vmp). Thus the actual Pmp point may not occur at exactly the Imp x Vmp. This can be corrected by entering new values for Imp and Vmp (see Figure A-1 in appendix A).

Also note that the accuracy specifications in simulator mode are relative to the values given in the exponential equations, and not necessarily to the input parameters Imp and Vmp. However, the Isc and Voc values are always accurately given by the exponential equations.

Restrictions:
- Maximum Power \( \leq 480 \text{ W} \)
- \( \text{Voc} \leq 130 \text{ V (E4351B)} \) or \( 65 \text{ V (E4350B)} \)
- \( \text{Isc} \leq 4 \text{ A (E4351B)} \) or \( 8 \text{ A (E4350B)} \)
- \( \text{Vmp} < \text{Voc} \)
- \( \text{Imp} \leq \text{Isc} \)
- \( \frac{\Delta V}{\Delta I} \geq 0.25 \Omega \) for Agilent E4350B; \( \geq 1 \Omega \) for Agilent E4351B

NOTE: When the unit detects invalid equation parameters, it will generate an error, light the ERR annunciator on the front panel, and will not use the new parameters. Instead, it will operate with the last valid settings. Therefore, although it may seem that the unit is operating correctly, it will NOT be using the values that you have programmed for simulator mode.

If simulator mode is entered with no parameters specified, the default values that will be used are:

<table>

</table>
Front panel operation:
You can use the front panel when the unit is operating in Simulator mode. To do this, press the **Local** key whenever the front panel **RMT** annunciator is on. Be aware however, that any voltage and current values that you enter from the front panel will have no effect on the unit while it is in Simulator mode. These front panel values will take effect as soon as the unit is placed in Fixed mode. Likewise, the OCP function only takes effect in Fixed mode. All other functions such as Local, Error, Output On/Off, Protect are active while the unit is operating in Simulator mode.

Table Mode

In Table mode, the output characteristic is determined by a user-defined table of voltage/current points (see Figure 1-3). Table mode operation is achieved by sampling the output voltage, applying a low-pass filter, and continually adjusting the constant current loop by using the filtered voltage as an index into the stored table of points. Linear interpolation is used to set the current when the filtered voltage does not have an exactly matching table entry. What this means is that the I-V curve is generated by connecting the points in the table by straight lines. The more points that you provide, the more accurate the curve will be when the points are connected.

![Figure 1-3. Table Mode Characteristic](image)

Each table can have a maximum of 4,000 output points (3,500 points if it will be stored in non-volatile memory). Each output point is defined by a voltage/current coordinate pair of values that define the location of the point on the curve. The first value is the voltage, the second value is the current. If no point is supplied for \( V = 0 \), the current associated with the lowest voltage entry point is defined as \( I_{sc} \) and the curve will be extended horizontally to the current axis. If no point is supplied for \( I = 0 \), the slope that was determined by the last two current entry points will be extended to the voltage axis.

Multiple tables can be defined and saved in non-volatile memory (which is limited to 3500 points), or volatile memory (which is limited to 30,000 points). Up to 30 tables can be saved in each memory.

Restrictions

- The number of points in a table can vary from 3 to 4000, but an equal number of voltage and current values must be sent. Otherwise an error will occur when the table is selected with CURRent:TABLe:NAME. Use MEMory:TABLe:CURRent:POINts? and MEMory:TABLe:VOLTage:POINts? to find the length of an existing table.
- Points must be above dashed line shown in Figure 1-3.
- There is no restriction on the spacing between points in either voltage or current, but the points must be monotonic.
  Voltage values must be sent in increasing order of magnitude; current values must be sent in equal or decreasing order
  of magnitude. For an Agilent E4350B for example: (1, 8) (50, 7.8) (55, 7.5) (56, 7) (57, 6) (58, 4) (59, 1).
- Each table point, when combined with the table offset, cannot exceed the unit’s maximum voltage, current, or power.
- A table cannot be deleted or redefined while it is selected with CURRent:TABLe:NAME.
- Maximum Power ≤ 480 W
- ΔV/ΔI ≥ .25 Ω for Agilent E4350B; ≥ 1 Ω for Agilent E4351B
  Voc ≤ 65V (Agilent E4350B); 130V (Agilent E4351B)
  Isc ≤ 8A (Agilent E4350B); 4A (Agilent E4351B)
  The Vmp and Imp points are calculated internally and need not be supplied.

**NOTE:** When the unit detects an invalid voltage/current point, it will generate an error, light the ERR annunciator on
the front panel, and will not use the new parameters. Instead, it will operate with the last valid table settings.
Therefore, although it may seem that the unit is operating correctly, it will **NOT** be using the values that you
have programmed for table mode.

### Table Offsets:
A new table can be generated by applying a limited voltage or current offset to an existing table. This can be helpful in
simulating temperature, angular, rotational, or aging changes. Offset values are non-cumulative, they can be either positive
or negative, and can be applied to any table. Each time a voltage or current offset is programmed, a new I-V curve is
calculated based on the user-defined table that is presently active and the supplied offset values. Offset values affect the
original I-V curve as follows:

**Positive Voltage Offsets:**
The original curve is shifted to the right (→) along the positive voltage axis, and the first
point on the curve is extended horizontally at Isc until it intersects the current axis. Thus,
the new Voc equals the original Voc plus the offset value. An error will be generated if the
offset causes the maximum allowed Voc or the power limit to be exceeded.

**Negative Voltage Offsets:**
The original curve is offset to the left (←) along the positive voltage axis, and terminated at
the current axis. The curve points that are not used because they extended beyond the
current axis are not deleted; they will be valid once again if the negative voltage offset is
reduced or eliminated.

**Positive Current Offsets:**
The original curve is offset up (↑) along the positive current axis, and the last point on the
curve will be extended (at the same slope that was present in the original table curve at
Voc) until it intersects the voltage axis at a new, slightly higher Voc value. The new Isc
equals the original Isc plus the offset value. An error will be generated if the offset causes
the maximum allowed Isc, Voc, or the power limit to be exceeded.

**Negative Current Offsets:**
The original curve is offset down (↓) along the positive current axis, and terminated at the
voltage axis at a new, lower Voc value. The curve points that are not used because they are
extended beyond the voltage axis are not deleted; they will be valid once again if the
negative current offset is reduced or eliminated.

### Front panel operation:
You can use the front panel when the unit is operating in Table mode. To do this, press the **Local** key whenever the front
panel RMT annunciator is on. Be aware however, that any voltage and current values that you enter from the front panel
will have no effect on the unit while it is in Table mode. The front panel values will take effect as soon as the unit is placed
in Fixed mode. Likewise, the OCP function only takes effect in Fixed mode. All other functions such as Local, Error,
Output On/Off, Protect are active while the unit is operating in Simulator mode.
Installation

Inspection

Damage

When you receive your Agilent SAS, inspect it for any obvious damage that may have occurred during shipment. If there is damage, notify the shipping carrier and the nearest Agilent Sales and Support Office immediately. Warranty information is printed in the front of this guide.

Packaging Material

Until you have checked out the Agilent SAS, save the shipping carton and packing materials in case the Agilent SAS has to be returned to Agilent Technologies. If you return the Agilent SAS for service, attach a tag identifying the model number and the owner. Also include a brief description of the problem.

Items Supplied

In addition to this manual, check that the following items in Table 2-1 are included with your Agilent SAS

<table>
<thead>
<tr>
<th>Table 2-1. Items Supplied</th>

</tr>
</tbody>
</table>

Location and Temperature

Bench Operation

The Supplemental Characteristics in appendix A give the dimensions of your Agilent SAS. The cabinet has plastic feet that are shaped to ensure self-alignment when stacked with other Agilent System II cabinets. The feet may be removed for rack mounting. Your Agilent SAS must be installed in a location that allows sufficient space at the sides and rear of the cabinet for adequate air circulation. Minimum clearances are 1 inch (25 mm) along the sides. Do not block the fan exhaust at the rear of the unit.
Rack Mounting

The Agilent SAS can be mounted in a standard 19-inch rack panel or cabinet. Rack mounting kits are available as Option 908 or 909 (with handles). Installation instructions are included with each rack mounting kit.

Support rails are required when rack-mounting the Agilent SAS (see table 1-1).

Temperature Performance

A variable-speed fan cools the unit by drawing air through the sides and exhaustin out the back. Using Agilent rack mount or slides will not impede the flow of air. The Agilent SAS operates without loss of performance within the temperature range of 0 °C to 40 °C and with derated output current from 40 °C to 55 °C (see appendix A).

WARNING
If the Agilent SAS is operated at full output current for several hours, the sheet metal immediately under the transformer (near the right front) can get very hot. Do not touch this area of the cabinet. The line cord also can become quite warm. Both of these conditions are normal.

AC Line Connection

Refer to the applicable paragraphs below for information on the ac line. Do not apply power to the Agilent SAS until directed to do so in Chapter 3.

CAUTION
Check the line Rating label on the rear of your unit and verify that the voltage shown there corresponds to the nominal line voltage of your ac line. If it does not, see AC Line Voltage Conversion for instructions on changing the Agilent SAS line voltage configuration.

The supplied cord connects to the power receptacle on the rear panel (②, Figure 2-1).

- You can operate your Agilent SAS from a nominal 100 V, 120 V, 220 V, 230 V, or 240 V single-phase ac line as indicated on the rear panel line Rating label ①.
- See "AC Input Ratings" in table A-1 or table A-2 in appendix A for the voltage and frequency range for the Agilent SAS. Refer to "Maximum AC Line Current Ratings" for the maximum load current.
- The line fuse is located in a fuseholder on the rear panel ③. The rear panel label shows the fuse value used in the unit. See Operator Replaceable Parts in chapter 1 for replacement fuse information.

Figure 2-1. Agilent SAS Power Connection
**AC Line Voltage Conversion**

**WARNING** SHOCK HAZARD. Hazardous voltage can remain inside the unit even after it has been turned off. This procedure should only be done by qualified electronics service personnel.

Line voltage conversion is accomplished by changing wire and jumper positions on the ac input of the main power transformer. Proceed as follows:

1. Turn off the ac power to the unit and disconnect the power cord from the ac line.
2. Remove the four screws that secure the two carrying straps and outer cover.
3. Slightly spread the bottom rear of the cover and pull it back to disengage it from the front panel.
4. Slide the dust cover back far enough to expose the line select jumpers (see figure 2-2).
5. Move the line voltage select jumpers to the positions corresponding to the desired line voltage. To disconnect it from the transformer tab, pull the wire straight up. Moving the wire from side-to-side can damage the tab.
6. Replace the top cover and secure the carrying straps.
7. Change the line fuse (on the rear panel) to the proper value for the new line voltage.

![Figure 2-2. Agilent SAS Line Select Jumpers](image)

**VXI plug&play Power Products Instrument Drivers**

VXI plug&play Power Products instrument drivers for Microsoft Windows 95 and Windows NT are now available on the Web at http://www.agilent.com/find/drivers. These instrument drivers provide a high-level programming interface to your Agilent Power Products instrument. VXI plug&play instrument drivers are an alternative to programming your instrument with SCPI command strings. Because the instrument driver’s function calls work together on top of the VISA I/O library, a single instrument driver can be used with multiple application environments.

**Supported Applications**

- Agilent VEE
- Microsoft Visual BASIC
- Microsoft Visual C/C++
- Borland C/C++
- National Instruments LabVIEW
- National Instruments LabWindows/CVI

**System Requirements**

The VXI plug&play Power Products instrument driver complies with the following:

- Microsoft Windows 95
- Microsoft Windows NT 4.0
- HP VISA revision F.01.02
- National Instruments VISA 1.1
Downloading and Installing the Driver

NOTE: Before installing the VXI plug&play instrument driver, make sure that you have one of the supported applications installed and running on your computer.

2. Select the instrument for which you need the driver.
3. Click on the driver, either Windows 95 or Windows NT, and download the executable file to your pc.
4. Locate the file that you downloaded from the Web. From the Start menu select Run <path>:\agxxxx.exe - where <path> is the directory path where the file is located, and agxxxx is the instrument driver that you downloaded.
5. Follow the directions on the screen to install the software. The default installation selections will work in most cases. The readme.txt file contains product updates or corrections that are not documented in the on-line help. If you decide to install this file, use any text editor to open and read it.
6. To use the VXI plug&play instrument driver, follow the directions in the VXI plug&play online help under “Introduction to Programming”.

Accessing Online Help

A comprehensive online programming reference is provided with the driver. It describes how to get started using the instrument driver with Agilent VEE, LabVIEW, and LabWindows. It includes complete descriptions of all function calls as well as example programs in C/C++ and Visual BASIC.

- To access the online help when you have chosen the default Vxipnp start folder, click on the Start button and select Programs | Vxipnp | Agxxxx Help (32-bit).
  - where Agxxxx is the instrument driver.
Turn-On Checkout

Introduction

Successful tests in this chapter provide a high degree of confidence that the Agilent SAS is operating properly. For verification tests, see appendix B under Verification. **Do not apply ac power to the Agilent SAS until told to do so.**

| Note | This chapter provides a preliminary introduction to the Agilent SAS front panel. See chapter 5 - Front Panel Operation for more details. During this procedure, the Agilent SAS is operating in Fixed mode. |

Preliminary Checkout

1. Make certain that the front panel switch is off.
2. Examine the Line Fuse Rating label on the rear panel.
   a. Verify that the line voltage rating agrees with your ac line. If it does not, see chapter 2 under AC Line Voltage Conversion.
   b. Use a screwdriver to remove the line fuse from the fuseholder. Verify that the fuse is as specified on the label. Replace the fuse.
3. Check that the SENSE switch is set to Local.
4. Make sure that there is no load connected to the output terminals or bus bars.

Power-On Checkout

1. Connect the power cord to the unit.
2. Turn the front panel power switch to ON (1).
3. The Agilent SAS undergoes a self-test when you turn it on. If the test is normal, the following sequence appears on the LCD:
   a. * * * * * a brief star-burst pattern which lights all the LCDs, followed by
   b. ADDR 5 the GPIB address (factory default is 5).
4. The display then goes into the meter mode with the Dis annunciator on and all others off. “Meter mode” means that the VOLTS digits indicate the output voltage and the AMPS digits indicate the output current. These values will be at or near zero.
5. Verify that the Agilent SAS fan is on by placing your hand near the rear grill to feel the air flow. You may also be able to hear the fan operating.
6. Press **Output on/off** once. The Dis annunciator will go off and the CV annunciator will go on.

| Note | If the Agilent SAS detects an error during self-test, the display will show an error message. Go to “In Case of Trouble” at the end of this chapter. |
Using The Keypad

Shifted Keys
Some of the front panel keys perform two functions, one labeled in black and the other in blue. You access the blue function by first pressing the blue Shift key, which is not labeled. When the Shift annunciator is on, you will know you have access to the key’s shifted (blue) function.

Backspace Key
The key is an erase key. If you make a mistake entering a number and have not yet entered it (have not pressed Enter), you can delete the number by pressing . You may delete as many numbers as you wish by repeatedly pressing this key.

Output Checkout

Important  When the Agilent SAS is turned on, it asserts the state stored in EEPROM memory location 0. For a new unit, this is the factory default (*RST) state. The following procedures assume that the factory default state is still in location 0 (see Turn-On Conditions in chapter 5 for details).

Checking the Voltage Function

The tests in Table 3-1 check the basic voltage functions with no load connected to the Agilent SAS. These tests are possible only from the front panel when the unit is operating in Fixed mode. The VOLTS display will show various readings. Ignore the AMPS display.

<table>

<td><strong>40.00</strong></td>
<td>The OVP circuit is cleared, restoring the output. <strong>Prot</strong> turns off and <strong>CV</strong> turns on.</td>
</tr>
</tbody>
</table>

* (**Shift**) is the unlabeled blue key.

Checking the Current Function

The tests in Table 3-2 check the basic current functions with a short connected across the Agilent SAS output. These tests are possible only from the front panel when the unit is operating in Fixed mode. Do not program maximum output currents unless the shorting wire is capable of handling the current (see Supplemental Characteristics in appendix A and Table 4-1). The **AMPS** display will show various readings. Ignore the **VOLTS** display.

</tr>
<tr>
<td>Press</td>
<td><strong>Output on/off</strong></td>
<td><strong>Dis</strong> turns off and <strong>CC</strong> turns on. The output current is restored.</td>
</tr>
</tbody>
</table>

*If you have a shorting wire of sufficient capacity, you may continue testing up to the maximum rated current of the Agilent SAS (see Performance Specifications in appendix A). When finished, go to the next step.*

*Press **Output on/off** | AMPS 0.000 | **Dis** turns on and output current drops to zero.  

Turn off the Agilent SAS and remove the short from the output terminals.

*(Shift) is the unlabeled blue key.*
Checking The Save And Recall Functions

The Save and Recall functions are applicable to the Agilent SAS in Fixed mode only. Note that in Simulator or in Table modes, the Save function is ignored, the recall will return the unit to the Fixed mode and reset the parameters to the *RST values (refer to the discussion of *RCL in chapter 7). The Agilent SAS has five nonvolatile memory storage locations (0 through 4). Proceed as follows:

- Make certain that the output is on (Dis annunciator is off).
- Set the voltage output to 5 by pressing \texttt{Voltage 5 Enter}.
- Save this value to location 1 by pressing \texttt{Shift Save 1 Enter}.
- Return the output voltage to 0 by pressing \texttt{Recall 0 Enter} (This step is based on the fact that a newly shipped Agilent SAS has the *RST parameters stored in location 0 (see chapter 5 - Front Panel Operation for more information).
- Press \texttt{Recall 1 Enter} and notice that the output voltage returns to the value stored in location 1.

Determining The GPIB Address

When the Agilent SAS is turned on, the display shows ADDR n, where n is the Agilent SAS GPIB address. Any time you want to see the address, press \texttt{Address}.

The display will indicate ADDR 5, which is the factory default. If the address has been changed, then a different number will appear (see Setting the GPIB Address in chapter 5).

In Case Of Trouble

Line Fuse
If your unit appears dead with a blank display and the fan not running, first check your ac line to be certain that voltage is being supplied to the Agilent SAS. If the power source is normal, the Agilent SAS line fuse may be defective. If the unit has a defective fuse, replace it only once. If it fails again, investigate the reason for the failure.

The line fuse is located on the rear panel. To change the fuse proceed as follows:
1. Turn off the front panel power switch.
2. Using a screwdriver, remove the fuse from the fuseholder. Replace it with one of the same type (see table 1-3 in chapter 1).
3. Turn on the Agilent SAS and check the operation.

Error Messages
Agilent SAS failure may occur during power-on selftest or during operation. In either case, the display may show an error message that indicates the reason for the failure.

Selftest Errors
When a selftest error occurs, it prevents all front panel operation. The display may show either a power-on error message or a checksum error message.

Power-On Error Messages
Power-on messages appear as:

\texttt{En- - - - -}

Where “n” is a number listed in Table 3-3. If this occurs, turn the power off and then back on to see if the error persists. It is possible to recover from the EE CHKSUM error (see “Checksum Errors”). If any other message persists, the Agilent SAS requires service.

</table>

### Checksum Errors.

If the display shows **EE CHKSUM**, the Agilent SAS has detected an EEPROM checksum error. A checksum error can occur due to the following conditions:

- Excessive number of write cycles to an EEPROM (see "Supplemental Characteristics"). This condition, which would appear only after extended use, is not recoverable and requires service.
- Loss of ac input power during a checksum calculation. This condition, which is very unlikely, is recoverable.

You may be able to recover from a checksum error by writing to the EEPROM while the Agilent SAS is in the calibration mode. To do this, proceed as follows:

1. Enable the calibration mode by pressing `Shift Cal Enable 1 Enter`.
2. `PASWD` will appear on the display.
3. Press the number keys corresponding to the password, followed by `Enter`. The `Cal` annunciator will go on.

### Note

On new equipment, the default calibration password corresponds to the model number (such as 4350). See appendix B under Changing the Calibration Password for more information.

4. Save any operating state (for example, press `Shift Save 0 Enter`).
5. Turn the power off and then back on.

A normal display free of error messages should appear. If not, the Agilent SAS requires service.

### Runtime Error Messages

Under unusual operating conditions, the **VOLT** or **AMPS** display may show `+OL` or `-OL`. This indicates that either the output voltage or current is beyond the range of the meter readback circuit, or that the value that is programmed is out of range. Table 3-4 shows other error messages that may appear at runtime.

User Connections

Rear Panel Connections

Make application load connections to the output terminals or bus bars, analog connector, and digital connector as shown on the rear-panel drawing for your model Agilent SAS. Make controller connections (GPIB and serial link) as shown in Figure 4-12 at the end of this chapter.

Wire Selection

**Fire Hazard** To satisfy safety requirements, load wires must be large enough not to overheat when carrying the maximum short-circuit current of the Agilent SAS. If there is more than one load, then any pair of load wires must be capable of safely carrying the full-rated current of the unit.

Table 4-1 lists the characteristics of AWG (American Wire Gauge) copper wire.

<table>

Figure 4-1. Rear Panel Analog Connector

**Note**

It is good engineering practice to twist or shield all signal wires to and from the analog and digital connectors.

To minimize spurious operation, make sure that all analog wiring except for the + and − sense wires does not exceed 3 meters in length.
Digital Connector

This connector, which is on the rear panel, is for connecting fault/inhibit, digital I/O, or relay link signals. The connector accepts wires sizes from AWG 22 to AWG 12.

Figure 4-2. Rear Panel Digital Connector

Load Connections

Output Isolation

The output of the Agilent SAS has dc isolation from earth ground. Either output terminal may be grounded, or an external voltage source may be connected between either output and ground. However, both output terminals must be kept within ±240 Vdc of ground. An earth ground terminal is provided on the rear panel for convenience, such as grounding wire shields.

WARNING The earth ground terminal on the rear panel is a low-noise signal ground for convenience only. It is not designed to function as a safety ground.

Capacitive Loads

In Fixed Mode Operation, the maximum external capacitance that may be added to the output without causing instability is 2,000 µF. This is also the maximum capacitance value that can be safely discharged by the OVP (overvoltage protection) circuit.
Because of its high output voltage, the Agilent E4351B generates high currents when discharging the load capacitor under overvoltage conditions. Excessive currents can damage the unit. The peak discharge current is limited by the sum of the external capacitor's ESR (equivalent series resistance) and the series resistance of the external circuit. For the Agilent E4351B's external capacitance limit of 2,000 µF, the total resistance must not be less than 56 milliohms. For smaller values of external capacitance, the total resistance may be derated linearly.

**Inductive Loads**

When operating in Simulator mode, load inductance should be kept under 200 µH. For twisted pair wires or zipcord, figure approximately 0.25 µH per foot of load lead wire.

**Connecting to an External Voltage Source**

The Agilent SAS's overvoltage circuit contains a crowbar SCR that effectively shorts the output of the unit whenever OVP trips.

**Note**

If the OVP trips, you must remove any external source of current in order to reset the internal SCR as part of clearing the OVP circuit (see Clearing the OV Condition in chapter 8).

If an external voltage source such as a battery is connected across the output and the OVP is inadvertently triggered, the Agilent SAS will continuously sink a large current from the source. This could damage the Agilent SAS. To avoid this, insert a reverse blocking diode in series with either output of the Agilent SAS in the direction of normal output current flow. The diode's voltage rating should be at least 150% of the HP SAS’s output voltage rating. The diode may also require a heat sink.

**Sense Connections**

Your Agilent SAS was shipped set up for local sensing. This means that the unit will sense and regulate its output voltage at the output terminals, with the load voltage being somewhat lower due to load lead voltage drop. Where load voltage regulation is critical, remote sensing may be required.

Local sensing is obtained by placing the SENSE switch (see Figure 4-3) in the **Local** position (button in). The Agilent SAS is shipped with the switch in this position.

**Note**

If the sense terminals are left unconnected with the sense switch in the Remote position, the voltage at the output will increase approximately 3 to 5% over the programmed value. Since the front panel meter measures the output voltage at the sense terminals, the voltage readback will not reflect this increase.

**Remote Voltage Sensing**

Optional Remote sense connections are illustrated in most of the load diagrams. Remote sensing is accomplished by connecting the remote sense terminals of the Agilent SAS directly to the load rather than to the output terminals. This allows the unit to automatically compensate for the voltage drop in the load leads as well as to accurately read back the voltage directly across the load.

In Fixed mode, the maximum allowable load lead drop that can be compensated for by remote sensing is 2 V.
In Simulator and Table mode, the maximum allowable voltage drop in the load leads is 2 V + (Voc - Vmp).

The Agilent SAS is shipped with the switch in the **Local** position. Remote sensing is obtained by placing the SENSE switch (see Figure 4-3) in the **Remote** position. Connect the positive side of the load to the +S analog connector pin and the negative side of the load to the -S analog connector pin (see Figure 4-1). Connect the sense leads carefully so that they do not become open-circuited. If sense leads are left open during operation, the unit will regulate at the output terminals instead.
of at the load, but with a 3% to 5% increase in voltage at the output terminals. Bundle or tie wrap the load leads to minimize inductance and reduce noise pickup.

**CV Regulation**

The Fixed mode voltage load regulation specification in appendix A applies at the output terminals of the Agilent SAS. When remote sensing, this specification must be adjusted by adding 3 mV to the voltage load regulation specification for each 1-volt change in the positive load lead due to a change in load current.

Because the sense leads are also part of the unit’s feedback path, keep the resistance of the sense leads low in order to obtain the best performance. The additional load regulation due to resistance in the sense leads is given by the formula:

\[
\text{Regulation in millivolts} = \frac{(\text{total load lead drop}) \times (\text{total sense lead resistance})}{K}
\]

where \( K = 3 \) for E4350B; 7 for E4351B

**Overvoltage Protection Considerations**

The OVP circuit senses the voltage at the output terminals, not at the sense terminals. With remote sensing, the voltage sensed by the OVP circuit will be higher than the voltage being maintained at the load. Therefore, when using remote sensing, you must program the OVP high enough to compensate for the expected voltage drop between the output and the load.

**Output Rating**

The rated output voltage and current specification in appendix A applies at the output terminals of the Agilent SAS. With remote sensing, any voltage dropped in the load leads causes the unit to increase the voltage at the output terminals so it can maintain the proper voltage at the load (see Remote Voltage Sensing). If you attempt to operate at the full-rated output at the load, this may force the voltage at the output terminals to exceed the unit’s rated output.

This will not damage the unit, but may trip the OVP (overvoltage protection) circuit, which senses the voltage at the output. When operated beyond its rated output, the unit’s performance specifications are not guaranteed, although typical performance may be good. If the excessive demand on the unit forces it to lose regulation, the Unr annunciator will indicate that the output is unregulated.

**Output Noise**

Any noise picked up on the sense leads also appears at the output of the Agilent SAS and may adversely affect the load voltage regulation. Be sure to twist the sense leads to minimize external noise pickup and route them parallel and close to the load leads. In noisy environments, it may be necessary to shield the sense leads. Ground the shield only at the Agilent SAS. Do not use the shield as one of the sense conductors.

**Stability**

In Simulator and Table modes, the unit is stable with constant current, constant resistance, constant voltage, and any capacitive loads. Inductive loads should be kept less than 200\( \mu \)H.

In Fixed mode, the unit is stable if the output capacitance is less than 2000\( \mu \)F.
Over Current Protection Considerations

The front panel overcurrent protection (OCP) is functional only when the Agilent SAS is operating in Fixed mode. This is because the normal function of the OCP circuit, when enabled, is to turn the output of the Agilent SAS off whenever the unit changes from constant voltage operation to constant current operation. Since constant current mode is the normal operating state of both Simulator and Table modes, the OCP key is disabled to prevent the output from turning off. Note that even though OCP is disabled, the OCP annunciator still lights when the OCP key is pushed in Simulator and Table modes.

The OCP protection level is the same as the output current limit setting. When the OCP is enabled in Fixed mode and the operating mode of the unit changes from constant voltage to constant current, the OCP circuit trips and turns the output off in approximately 200 milliseconds. This delay time can be adjusted with the OUTPut:PROTection:DELay command. The PROT annunciator on the front panel display turns on when the OCP condition occurs. When reading the protection message in the front panel display, the reading will be OC.

Clear the OCP condition by pressing Prot Clear on the front panel or by sending an OUTPut:PROTection:CLEar command over the GPIB. Note that you can program an OUTPut:PROTection:DELay time to prevent nuisance tripping of the OCP circuit when it is enabled.

Hardware Overcurrent Circuit (OC)

The Agilent SAS has a hardware overcurrent circuit (OC) that protects the unit if the output current exceeds a preset value. Although active in all operating modes, this circuit is primarily provided for the Simulator and Table modes since both of these modes disable the constant-current OCP function. When tripped, the OC circuit shuts off the output and fires the internal SCR in approximately 50 to 100 microseconds.

Note

The OC circuit limit can only be programmed over the GPIB using the CURRent:PROTection command. You cannot set the OC limit from the front panel, and you cannot program a delay time for this circuit.

When an overcurrent condition occurs in Simulator and Table modes, the PROT annunciator on the front panel display will turn on. The protect message reading on the front panel display will be OV OC. To return the Agilent SAS to normal operation, first remove the cause of the overcurrent. Then either press Prot Clear on the front panel or send an OUTPut:PROTection:CLEar command over the GPIB.

Operating Configurations

Connecting the Load to One Unit

Figures 4-4 and 4-5 show how to connect a single Agilent SAS to one load and to multiple loads.

![Figure 4-4. Single Load Connection](image-url)
Connecting Supplies in Parallel

In most cases, units can be connected in straight parallel mode as shown in Figure 4-6 without any master/slave distinction, and without any wiring to the analog connectors. This is possible because of the relatively high output impedance of each unit. All units that are connected in straight parallel mode must be programmed with identical I-V curves or table data. Remote sensing may be employed on all units if desired, but in many cases will have only a minimal effect on performance due to the high output impedance of each unit.

If, for some reason, it is required that the output currents of all paralleled units be accurately matched, then you must use auto-parallel connections as described in the following paragraphs.
Connecting Supplies in Auto-Parallel

Auto-parallel connections are used only if it is required that the output currents of all paralleled units be accurately matched. Otherwise you can use straight parallel connections as described in the previous paragraphs.

Auto-Parallel Wiring in Simulator and Table Modes

Figure 4-7 illustrates how units can be connected in auto-parallel for increased current output in Simulator and Table modes. If remote sensing is required, connect the remote sense terminals of all the supplies to the load as shown in Figure 4-7.

<table>
<thead>
<tr>
<th>① Analog Connectors</th>
<th>② Slave Units</th>
<th>③ Master Unit</th>
<th>④ Load</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set all units to either local sensing or remote sensing.</td>
<td>Optional remote sense connections</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that because there is already an output impedance associated with the units in Simulator and Table modes, in many cases remote sensing has little effect especially if the load lead resistance is kept low.

Figure 4-7. Auto-Parallel Connection in Simulator Mode (Remote Sensing Optional)

Auto-Parallel Programming in Simulator and Table modes

When operating in Simulator mode, all units must be programmed with identical curves. However the Isc and Imp values sent to the slave units must be set to zero (0). This is because in auto-parallel mode, the master unit controls the output current of the slave units. When operating in Table mode, all units must be programmed with identical table data. However, you must append a value of -999 at the end of the current data and a value of +999 at the end of the voltage data for slave units. This again allows the master unit to control the output current of the slave units. Refer to chapter 6 under Programming Units in Auto-parallel for a programming example.

Auto-Parallel Wiring in Fixed Mode

Figure 4-8 illustrates how units can be connected in auto-parallel for increased current output with current sharing. If remote sensing is required, connect the remote sense terminals of the master unit to the load as shown in Figure 4-8. To avoid output ringing, you can either connect a 2.2 μF or larger capacitor across the load, or you can connect a filter across the current monitoring connections as shown in the figure. This network consists of two 200 ohm resistors in series with the current monitoring lines going to the master unit, and a 68 ohm/0.1μF RC paralleled across + and − IP terminals.
### Auto-Parallel Programming in Fixed mode

Program only the first or "master" unit in the series; the current of the "slave" units automatically track the master's current. Set the slave unit's current limit to zero and its voltage and OVP settings higher than the maximum voltage setting of the master unit. This ensures that the slave supplies will operate in CC mode. Functions such as status, voltage readback, and current readback can still be read back individually for each unit.

### Auto-Parallel Programming Cautions

**Caution**

To avoid possible tripping of the crowbar SCR, do not turn power off on auto-parallel units while they are operating in Simulator or Table mode. Reprogram all units to Fixed mode and set the voltage to zero before turning them off.

If a "slave" unit experiences a shutdown condition such as overtemperature or overcurrent, it will **not** automatically shut down other units unless you have connected and enabled the remote inhibit (RI) and discrete fault indicator (DFI) operation. See appendix C and Questionable Status group in chapter 8.

Also use caution when connecting three or more Agilent SAS units for auto-parallel operation because of the OVP crowbar circuits. If the OVP circuit of any unit trips, its crowbar circuit will draw current from all of the other units. Depending on the number of units, the additional current may damage the internal SCR of the tripped unit. Use one of the following techniques to avoid problems.

1. **Program the OVP of all slave units to the Maximum Level.** This minimizes the chance that the slave OVP circuits will trip. Then program the OVP level of the master unit to the desired protection level (below the maximum level specified in table 7-3).

2. **Insert Protection Diodes.** If you connect all supplies to the load through a series diode (see Figure 4-9) and a unit's crowbar SCR trips, it will not draw current from other supplies. Be certain to increase the programmed voltage level of the slaves by at least 0.7 V to compensate for the voltage drop in the diode.
3. **Remove or disable the Agilent SAS OVP crowbar SCR.** For further information, contact an Agilent Service Engineer through your local Agilent Sales and Support Office.

![Figure 4-9. Using Series Diodes with Auto-Parallel Operation](image)

**Connecting Supplies in Series**

**WARNING** Only connect units in series that have identical voltage and current ratings. Floating voltages must not exceed ±240 Vdc. No output terminal may be more than 240V from chassis ground. When operating in Simulator mode, units must be programmed with identical curves. When operating in Table mode, units must be programmed with identical table data.

Figure 4-10 shows how Agilent SAS units can be connected in series for higher voltage output. Series connections are straightforward in this case. Program each Agilent SAS independently. In **Fixed** mode, program each unit for 50% of the total output voltage. Set the current limit of each unit to the maximum that the load can handle without damage. In **Simulator** mode, the total Voc that will be provided is the sum of the open circuit voltages programmed for each individual unit.

**CAUTION** Each Agilent SAS has a reverse voltage protection diode across its output. If a reverse voltage is applied, the unit cannot control the current conducted through this diode. To avoid damaging the unit, never connect it in such a way that a reverse voltage can force it to conduct current in excess of the unit's output current rating.

<td>Optional remote sense connections</td>
</tr>
</tbody>
</table>
Analog Current Control (applies in Fixed mode only)

The setup shown in Figure 4-11 allows an external dc voltage to program the Agilent SAS output current in Fixed mode. A voltage applied to the differential current programming input programs the output current. Note that depending on the polarity of the external source, the external signal is either added to or subtracted from the front panel current setting. Output current is internally limited to a maximum of ≈112% of the output current rating. If you want to fully control the output current through the analog input, you must first set the front panel current control to zero. A voltage of 0 to 4 volts programs the output current from zero amperes to the rated output current.

For proper operation, the maximum common-mode voltage between either the +IP or -IP inputs and the +OUT terminal should be kept to less than ±18 volts. Note also that the input impedance of the analog input is 20 kΩ. If the output impedance of your programming source is not negligible compared to 20 kΩ, the programmed current will be less than expected.

Wiring Considerations

Be careful of capacitive coupling from the programming inputs to other lines wired to the analog connector. Such coupling can cause output oscillations and noise. You can minimize coupling by bundling the +IP and -IP lines and keeping them separated from other wires. Twisting these lines together is also recommended.

Controller Connections

Figure 4-12 shows two basic ways of connecting your Agilent SAS to a controller. They are “linked” and “stand-alone configurations.

Stand-Alone Connections

See Figure 4-12A. Each stand-alone Agilent SAS has its own GPIB bus address. Stand-alone units may be connected to the bus in series configuration, star configuration, or a combination of the two. You may connect from 1 to 15 stand-alone units to a controller GPIB interface.

Linked Connections

See Figure 4-12B. Up to 16 units may be used at a single GPIB primary bus address by making linked connections.

- The first Agilent SAS in a linked connection is a “direct unit” connected to the controller via a GPIB cable. The direct unit is the only unit connected directly to the bus and has a unique primary bus address.
- The remaining units are “linked supplies” connected to the direct unit via a serial-link cable. Each linked unit has a unique secondary GPIB address and derives its primary address from the direct unit. You may connect from 1 to 15 linked supplies to each direct unit.
The Agilent SAS is shipped from the factory with its GPIB address set to 5. The Agilent SAS primary and secondary addresses can be changed from the front panel as described under Changing the GPIB Address in chapter 5. For Agilent SAS GPIB interface capabilities, see appendix A.

Note on page 39:

1. From 1 to 15 direct supplies may be connected to 1 controller GPIB interface.
2. Tighten connector thumbscrews by hand. Do not use a screwdriver.
3. Do not stack more than 3 connectors on a GPIB receptacle.
4. GPIB cable (see Accessories in Chapter 1)
5. From 1 to 15 linked supplies may be connected to 1 direct unit.
6. Either receptacle (J1 or J2) may be used as an input or an output.
7. Serial Link Cable (see Accessories in Chapter 1), 2 meters. 1 is supplied.
   * Maximum total length of all GPIB cables (including controller) not to exceed 20 meters.
   * Use caution with individual lengths over 4 meters.
   * Maximum total length of all serial cables not to exceed 30 meters.

NOTES:
1. A direct Agilent SAS is connected to the controller interface and must have a unique primary GPIB bus address.
2. The stand-alone configuration uses only direct supplies connected to the controller interface.
3. The linked configuration uses 1 or more linked units connected to each direct unit. Each linked unit has a unique secondary GPIB bus address and derives its primary address from the direct unit.

Figure 4-12. Controller Connections
Front Panel Operation

Introduction

Note  Only in Fixed mode are front panel operations fully functional. The Agilent SAS can be operated as a standard dc source in Fixed mode. SAS functions are available when the unit is set to Simulator or Table mode. You cannot switch modes from the front panel. Modes can only be switched over the GPIB.

This chapter shows you how to operate the unit from front panel. It is assumed that you are familiar with the turn-on checkout procedure in chapter 3. That chapter describes how to perform basic functions from the control panel. Operations that you can perform are:
- Enabling or disabling the Agilent SAS output.
- Setting the output voltage and current.
- Monitoring the output voltage and current.
- Setting the overvoltage protection trip point.
- Enabling the overcurrent protection circuit (OCP).
- Clearing protection functions.
- Saving operating states in nonvolatile memory.
- Recalling operating states from nonvolatile memory.
- Setting the Agilent SAS GPIB bus address.
- Displaying error codes created during remote operation.
- Enabling local (front panel) operation.
- Calibration (see appendix B).

Key Functions

The front panel is summarized in Figure 5-1 and Table 5-1. Some keys have two functions. For example, the Systemkey can be used either to recall a stored operating state or to (store) an operating state. The first operation is shown on the key and the second (shifted) operation is shown in blue above the key. In order to do a shifted operation, first press the solid blue key, which is unlabeled but shown throughout this manual as Shift.

For example, for a recall operation, press the recall key Recall. For a save operation, press the Save key, which is Shift Recall. When you do this, the Shift annunciator will light to remind you that the Recall key is now functioning as the Save key. In this chapter, such a shifted operation may be shown simply as Save.

Programming the Output

**Important** These instructions show how to program a single Agilent SAS from the front panel. These instructions apply primarily when the unit is set to operate in Fixed mode. For example, any voltage and current values that you enter from the front panel will have no effect on the unit while it is in Simulator or Table modes but will take effect as soon as the unit is placed in Fixed mode. Likewise, the OCP function only takes effect in Fixed mode. There are also special considerations when you have two or more supplies connected in series or in parallel. See chapter 4 - User Connections and Considerations.

The Agilent SAS accepts values directly in volts and amperes. Values will be rounded off to the nearest multiple of the output resolution (see “Average Resolution” in appendix A). If you attempt to enter a value not in a valid range, the entry will be ignored and **OUT OF RANGE** appears on the display.

Figure 1-1 on page 1-3 shows the general response of a typical unit in Fixed mode. Always keep the output voltage and current within the boundaries of its operating line for the specified mode of operation (CV or CC).

**Establishing Initial Conditions**

Set the Agilent SAS to its **RST** state by pressing **Recall 0 Enter**. This state was stored in location 0 at the factory. If it has since been changed, you can restore it as directed under “Turn-on Conditions”, later in this chapter. **RST** results in the following operating conditions:

- Zero voltage output.
- Minimal current output.
- Output disabled (**Dis** annunciator on).
- Overvoltage protection set to its maximum value.
- Overcurrent protection off (**OCP** annunciator off).
- Hardware overcurrent protection set to its maximum value.
- Protection circuits cleared (**Prot** annunciator off).

**Programming Voltage**

To program the output for 45 volts, proceed as follows:

- Press **Voltage**. The display will change from meter mode to indicate **VOLTS**.
- Press **4 3 Enter**. If you discover a mistake before pressing **Enter**, erase the incorrect value with the backspace key.
- The display will return to the meter mode and indicate 00.00 volts.
- Press **Output On/Off** to enable the output (**Dis** annunciator turns off). The **VOLTS** display will indicate 45.0 volts.

**Note** The Agilent SAS must be programmed for a minimal current in order to increase the output voltage beyond zero. If the Agilent SAS does not respond or the **CC** annunciator turns on, go to “Programming Current” and set the current to a small value.

- Now raise the voltage by pressing **Voltage**. Note that the voltage increases by a specific increment (depending on the voltage programming resolution) each time you press the key and increases rapidly as you hold down the key. To lower the voltage, press **Voltage**.
- Try raising and lowering the voltage by rotating the **Voltage** control clockwise and then counterclockwise. Note how the output responds as compared to using the **Entry** keys.

Try to program a voltage greater than the maximum voltage rating for your unit (see Supplemental Characteristics in appendix A). Note that the display shows **OUT OF RANGE**.
Programming Current

You may program the Agilent SAS current without a load, but must have a load in order to draw output current. These tests assume you have the load connected in accordance with the information in chapter 4 - User Connections and Considerations. If you do not have a load on the Agilent SAS, you may connect a short across the output terminals as described in chapter 3 - Turn-on Checkout.

The example will program a low current. (You may later increase the output current to the levels you will expect to use.) To program the output current to 1.3 amperes, proceed as follows:

■ Disable the output by pressing \( \text{Output On/Off} \). The Dis annunciator will turn on.
■ Program the voltage by pressing \( \text{Voltage} \) \( \text{5} \) \( \text{3} \) \( \text{Enter} \).
■ Press \( \text{Current} \). The display will change from meter mode to indicate AMPS.
■ Press \( \text{1} \) \( \text{3} \) \( \text{Enter} \). If you discover a mistake before pressing \( \text{Enter} \) erase the incorrect value with the backspace key \( \text{ } \rangle \).
■ The display will return to the meter mode and indicate up to 0.000.
■ Press \( \text{Output On/Off} \) to enable the output. Dis will turn off and the display will indicate VOLTS 50.00 AMPS 1.300.
■ Now increase the current by pressing \( \text{Current} \). Note that the current increases by a specific increment (depending on the current programming resolution) each time you press the key and increases rapidly as you hold down the key. To decrease the current, press \( \text{Current} \). 
■ Try increasing and decreasing the current by rotating the Current knob clockwise and counterclockwise. Note how the output responds as compared to using the Entry keys.

Disable the output by pressing \( \text{Output On/Off} \). The Dis annunciator will turn on. Now try to program a current greater than the I.MAX for your unit. Note that the display shows OUT OF RANGE.

Programming Overvoltage Protection

Overvoltage protection guards the load against voltages that reach a specified value above the programmed output voltage.

Setting the OVP Level

Assuming that you have programmed the Agilent SAS for 45 volts, you can set the OVP level to 48 volts as follows:

■ Press \( \text{OV} \). The display will change from meter mode to indicate OV, followed by the present OVP value.
■ Press \( \text{4} \) \( \text{8} \) \( \text{Enter} \).
■ The display will return to the meter mode and indicate the output voltage (45.00 volts).
■ Press \( \text{OV} \) again. The display will now indicate OV 48.00.
■ Press \( \text{Enter} \) to return to the meter mode.

Checking OVP Operation

Assuming the above operating conditions (voltage programmed to 45 V and OVP programmed to 48 V), trip the OVP circuit as follows:

■ Gradually increase the output voltage by pressing \( \text{Voltage} \) until the OVP circuit trips. This will cause the output voltage to drop to zero and the Prot annunciator to go on.
■ There now is no Agilent SAS output due to an overvoltage condition.
■ To verify this, press \( \text{Protect} \) and observe that the display indicates OV. This shows that the protection circuit tripped due to an overvoltage condition.
Clearing The OVP Condition

With the OVP tripped, return to the meter mode and try to clear the condition by pressing Prot Clear. Nothing will appear to happen because the OV trip voltage is still below the programmed output voltage. Thus, as soon as the circuit is cleared, it trips again. You can clear the OV condition by:
- Lowering the output voltage below 48 (the OV setting), or
- By raising the OV trip voltage above the output voltage setting.

Try either of these methods. Now when you press Prot Clear, the Prot annunciator will turn off and the output voltage will return to normal.

Programming Overcurrent Protection

When enabled, overcurrent protection removes the Agilent SAS output whenever it goes into CC operation. This prevents the unit from indefinitely supplying the full programmed current to the load.

**Note**

This constant-current OCP feature is only available in Fixed mode. In Simulator and Tables modes, a hardware current limit protection circuit turns the unit off when a programmable current limit is reached. This current limit is only programmable over the GPIB using SOUR:CURR:PROT.

Setting The OCP Protection

To activate overcurrent protection, press OCP. The OCP annunciator will light and Agilent SAS will continue to operate normally until it is forced into CC operation. If that occurs, the OCP circuit trips and the Agilent SAS output drops to zero.

Checking OCP Operation

The easiest way to check this operation at any specified current is to increase the load current beyond the programmed current value. This will force the Agilent SAS into the CC mode. When OCP trips, the Prot annunciator will light and the Agilent SAS output will drop to zero.

There is now no Agilent SAS output due to an overcurrent condition. To verify this, press Protect and observe that the display indicates OC.

Clearing The OCP Condition

With the OCP tripped, return to the meter mode and try to clear the condition by pressing Prot Clear. Nothing will appear to happen because the reason for the condition has not been removed. Thus, as soon as the circuit is cleared, it trips again. You can clear the OC condition by:
- Increasing the load resistance to lower the output current below the programmed current value, or
- By raising the programmed current to a value above that required by the load.

Clear the fault by either of the above methods. Then clear the OCP circuit by pressing Prot Clear. The Prot annunciator will go off and the Agilent SAS output will be restored to normal. If desired, you can also restore the output by disabling the OCP function (press OCP to turn off the OCP annunciator). This restores the output but does not clear any condition that may have caused OCP to trip.

**Note**

Under certain conditions, the OCP circuit may fail to clear because load demand occurs before the Agilent SAS has time to build up the required output current capacity. In such cases, disable the output (press Output On/Off before clearing the OCP circuit). After OCP is cleared, then enable the Agilent SAS output.
**CV Mode VS. CC Mode**

Once you program a voltage ($V_{SET}$) and a current ($I_{SET}$), the Agilent SAS will maintain itself in either CV or CC mode, depending on the resistance of the load ($R_L$). If the load demands less current than $I_{SET}$, operation will be in CV mode with the voltage maintained at $V_{SET}$. The output current will be at some value below $I_{SET}$ as determined by $V_{SET} / R_L$.

If the current increases beyond $I_{SET}$, the unit will switch to CC mode by varying its output voltage to maintain a constant current value of $I_{SET}$. As the load resistance is decreased, the voltage decreases to maintain the set current level. In other words, the output voltage is determined by $V_{SET} \times R_L$.

**Unregulated Operation**

If the Agilent SAS goes into a mode of operation that is neither CV nor CC, the Unr annunciator will light. Some unregulated states occur so briefly that they do not turn on the Unr annunciator, but they may set the UNR status bit during remote operation (see chapter 6 under Programming Status). One condition that can cause a noticeable unregulated state is low ac line voltage. Another condition might be operation with a paralleled unit that has a different voltage setting.

**Saving and Recalling Operating States**

You can save programming time by storing up to five operating states in nonvolatile memory. The front panel programming parameters that are saved are:
- Output voltage
- Output current
- *OVP voltage.
- OCP state (on or off)
- Output state (enabled or disabled).

**Note**  More Agilent SAS parameters are saved in remote operation. See chapter 7 under *SAV.

As an example, set up the following state:
- Voltage = 4 V  Current = 5 A  OVP voltage = 4.5 V.
- OCP = on (OCP annunciator on)  Output = off (Dis annunciator on).

Save the above state to location 1 by pressing $\text{Save} \ 1 \ \text{Enter}$. Now set up the following state:
- Voltage = 4.5 V  Current = 2.5 A  OVP voltage = 5 V.
- OCP = off (OCP annunciator off)  Output = on (Dis annunciator off).

Save the above state to location 2 by pressing $\text{Save} \ 2 \ \text{Enter}$. Restore the first state by pressing $\text{Recall} \ 1 \ \text{Enter}$ and verify the parameters. Restore the second state by pressing $\text{Recall} \ 2 \ \text{Enter}$. Note how the Agilent SAS is automatically programmed each time.

**Turn-On Conditions**

Whenever you first apply power to an Agilent SAS it automatically turns on in a safe reset state, in Fixed mode, with the following parameters:
- Output off
- Voltage minimum*
- Current maximum
- OCP off

*Minimum is the *RST value specified in Table 7-3.

It is recommended that you leave the turn-on conditions as programmed. However, you may change them if you wish. To do this, proceed as follows:
1. Set up the Agilent SAS to the state you want when it is turned on.
2. Store that state to location 0.
3. Turn off the Agilent SAS.
4. Hold in the \[ \text{key} \] and turn the Agilent SAS back on. The display indicates \text{RCL 0 PWR-ON} to verify that the Agilent SAS has configured its turn-on state to that stored in location 0.
5. From now on the unit will always turn on to the state defined in location 0.

Whenever you wish, you can return the Agilent SAS to the original factory reset state. To do this, simply hold down the \[ 9 \] key when you turn on the unit. The display indicates \text{RST POWER-ON} to verify that the Agilent SAS has configured its turn-on state to the original reset state. From now on it will continue to turn on in that state.

---

**Setting The GPIB Address**

**Types of GPIB Addresses**

Figure 4-11 in chapter 4 shows the ways the Agilent SAS can be connected to the GPIB bus. You can set up the GPIB address in one of three ways:

1. As a stand-alone unit (the only unit at the address). It has a primary address in the range of 0 to 30. For example: 5 or 7.
2. As the direct unit in a serial link. It is the only unit connected directly to the GPIB bus. The primary address is unique and can be from 0 to 30. It is entered as an integer followed by a decimal separator. The secondary address always is 0, which may be added after the primary address. If the secondary address is omitted, it is assumed to be 0. For example: 5.0 or 7.
3. As a linked unit in serial link. It gets its primary address from the direct unit. It has a unique secondary address that can be from 1 to 15. It is entered as an integer preceded by a decimal separator. For example: .1 or .12

When you enter a secondary address, leading zeros between the decimal separator and the first digit are ignored. For example, .1, .01, and .001 are accepted as secondary address 1 and displayed as 0.01. Zeros following a digit are not ignored. Thus, .10 and .010 are both accepted as secondary address 10 and displayed as 0. 10.

**Changing the GPIB Address**

Use the \[ \text{Address} \] key and numerical keypad for entering addresses. The Agilent SAS is shipped with a 5 stand-alone address as the default. The general procedure for setting an address is:

<table>
<thead>
<tr>
<th>Action</th>
<th>Display Shows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press [ \text{Address} ]</td>
<td>Current address</td>
</tr>
<tr>
<td>Press new address keys</td>
<td>New address replaces numbers on the display</td>
</tr>
<tr>
<td>Press [ \text{Enter} ]</td>
<td>Display returns to meter mode</td>
</tr>
</tbody>
</table>

If you try to enter an invalid number, \text{ADDR ERROR} is displayed.

The following examples show how to set addresses:

- To set stand-along primary address 6, press \[ \text{Address} \ 6 \ \text{Enter} \]
- To set direct unit primary address 6, press \[ \text{Address} \ 6 \ \text{Enter} \]
- To set linked secondary address 1, press \[ \text{Address} \ 1 \ \text{Enter} \]
- To set linked secondary address 12, press \[ \text{Address} \ 1 \ 2 \ \text{Enter} \]

**Note**

The Agilent SAS display will reset (recall the state in location 0) whenever you change between a stand-alone primary address and a direct primary address, or a direct primary address and a secondary address.
Remote Programming

GPIB Capabilities of the Agilent SAS

All Agilent SAS functions except for setting the GPIB address are programmable over the IEEE 488 bus (also known as the General Purpose Interface Bus or "GPIB"). The IEEE 488.1 capabilities of the Agilent SAS are listed in the Supplemental Characteristics in appendix A. The Agilent SAS operates from a GPIB address that is set from the front panel (see System Considerations at the end of this chapter).

Introduction To SCPI

Important Learn the basics of Agilent SAS operation (see chapter 5 - Front Panel Operation) before using SCPI.

SCPI (Standard Commands for Programmable Instruments) is a programming language for controlling instrument functions over the GPIB (IEEE 488) instrument bus. SCPI is intended to function with standard GPIB hardware and conforms to the IEEE Standard Digital Interface for Programmable Instrumentation. SCPI is layered on top of the hardware portion of IEEE 488.2. The same SCPI commands and parameters control the same functions in different classes of instruments. For example, you would use the same DISPlay command to control the Agilent SAS display state and the display state of a SCPI-compatible multimeter.

Note TMSL (Test and Measurement System Language) was an earlier version of SCPI. If you have programmed in this language, then you probably can go directly to chapter 7 - Language Dictionary.

Conventions
The following conventions are used throughout this chapter:

Angle brackets < > Items within angle brackets are parameter abbreviations. For example, <NR1> indicates a specific form of numerical data.

Vertical bar | Vertical bars separate one of two or more alternative parameters. For example, 0|OFF indicates that you may enter either "0" or "OFF" for the required parameter.

Square Brackets [ ] Items within square brackets are optional. The representation [SOURce]:CURRent means that SOURce may be omitted.

Braces { } Braces indicate parameters that may be repeated zero or more times. It is used especially for showing arrays. The notation <A>{<B>} shows that "A" is a required parameter, while "B" may be omitted or may be entered one or more times.

Boldface font Boldface font is used to emphasize syntax in command definitions. TRIGger:DELay <NRf> shows a command syntax.

Computer font Computer font is used to show program text within normal text. TRIGger:DELay .5 represents program text.
Types of SCPI Commands

SCPI has two types of commands, common and subsystem.

- **Common** commands (see table 7-1) generally are not related to specific operation but to controlling overall Agilent SAS functions, such as reset, status, and synchronization. All common commands consist of a three-letter mnemonic preceded by an asterisk:
  
  *RST  *IDN?  *SRE 8

- **Subsystem** commands (see table 7-2) perform specific Agilent SAS functions. They are organized into an inverted tree structure with the "root" at the top. The following figure shows a portion of a subsystem command tree, from which you access the commands located along the various paths.

Figure 6-1 shows a portion of the subsystem command tree (you can see the complete tree in table 7-2). Note the location of the ROOT node at the top of the tree. The SCPI interface is at this location when:

- The Agilent SAS is powered on.
- A device clear (DCL) is sent to the Agilent SAS.
- The interface encounters a message terminator.
- The interface encounters a root specifier.

![Figure 6-1. Partial Command Tree](image)

Multiple Commands in a Message

Multiple SCPI commands can be combined and sent as a single message with one message terminator. There are two important considerations when sending several commands within a single message:

- Use a semicolon to separate commands within a message.
- There is an implied header path that affects how commands are interpreted by the Agilent SAS.

The header path can be thought of as a string that gets inserted before each command within a message. For the first command in a message, the header path is a null string. For each subsequent command the header path is defined as the characters that make up the headers of the previous command in the message up to and including the last colon separator.

An example of a message with two commands is:

```
CURR:LEV 3;PROT:STAT OFF
```

which shows the use of the semicolon separating the two commands, and also illustrates the header path concept. Note that with the second command, the leading header "CURR" was omitted because after the "CURR:LEV 3" command, the header path was became defined as "CURR" and thus the instrument interpreted the second command as:

```
CURR:PROT:STAT OFF
```

In fact, it would have been syntactically incorrect to include the "CURR" explicitly in the second command, since the result after combining it with the header path would be:

```
CURR:CURR:PROT:STAT OFF
```

which is incorrect.
Moving Among Subsystems

In order to combine commands from different subsystems, you need to be able to restore the active path to the root. You do this with the root specifier (:). For example, you could clear the output protection and check the status of the Operation Condition register as follows:

```
OUTPUT:PROTECTION:clear
STATUS:OPERATION:CONDITION?
```

By using the root specifier, you could do the same thing in one message (see figure 6-2):

```
OUTPUT:PROTECTION:clear;:STATUS:OPERATION:CONDITION?
```

The following message shows how to combine commands from different subsystems as well as within the same subsystem (see figure 6-2):

```
VOLTAGE:LEVEL 60;PROTECTION 65;:CURRENT:LEVEL 4;PROTECTION ON
```

Note the use of the optional header LEVEL to maintain the correct path within the voltage and current subsystems and the use of the root specifier to move between subsystems.

Value Coupling

Value coupling results when a command directed to send one parameter also changes the value of a second parameter. There is no direct coupling among any Agilent SAS SCPI commands. However, be aware that until they are programmed, uninitialized trigger levels will assume their corresponding immediate levels. For example, if a unit is powered up and VOLT:LEV is programmed to 60, then VOLT:LEV:TRIG will also be 60 until you program it to another value. Once you program VOLT:LEV:TRIG to another value, it will remain at that value regardless of how you subsequently reprogram VOLT:LEVEL.

Including Common Commands

You can combine common commands with system commands in the same message. Treat the common command as a message unit by separating it with the message unit separator. Common commands do not affect the active header path; you may insert them anywhere in the message.

```
VOLT:TRIG 55;INIT;*TRG
OUTP OFF;*RCL 2;OUTP ON
```

SCPI Queries

Observe the following precautions with queries:

- Remember to set up the proper number of variables for the returned data.
- Set the program to read back all the results of a query before sending another command to the Agilent SAS. Otherwise, a Query Interrupted error will occur and the unreturned data will be lost.

Types of SCPI Messages

There are two types of SCPI messages, program and response.

- A program message consists of one or more properly formatted SCPI commands sent from the controller to the Agilent SAS. The message, which may be sent at any time, requests the Agilent SAS to perform some action.
- A response message consists of data in a specific SCPI format sent from the Agilent SAS to the controller. The Agilent SAS sends the message only when commanded by a special program message called a "query."
The following figure illustrates the SCPI message structure:

![Diagram of SCPI message structure](image.png)

**Figure 6-2. Command Message Structure**

### The Message Unit

The simplest SCPI command is a single message unit consisting of a command header (or keyword) followed by a message terminator. The message unit may include a parameter after the header. The parameter can be numeric or a string.

```
ABOR<NL>
VOLT 20<NL>
```

**Headers**

*Headers* (which are sometimes known as "keywords") are instructions recognized by the programming interface. Headers may be either in the long form or the short form.

- **Long Form**: The header is completely spelled out, such as VOLTAGE STATUS DELAY.
- **Short Form**: The header has only the first three or four letters, such as VOLT STAT DEL.

**Query Indicator**

Following a header with a question mark turns it into a query (VOLT? VOLT:PROT?). If a query contains a parameter, place the query indicator at the end of the last header (VOLT:PROT? MAX).

**Message Unit Separator**

When two or more message units are combined into a compound message, separate the units with a semicolon (STATus:OPERation?;QUEStionable?).

**Root Specifier**

When it precedes the first header of a message unit, the colon becomes a "root specifier". This indicates that the command path is at the root or top node of the command tree.

**Message Terminator**

A terminator informs SCPI that it has reached the end of a message. Three permitted messages terminators are:

- Newline (<NL>), which is ASCII decimal 10 or hex 0A.
- End or identify (<END>)
- Both of the above (<NL><END>)

In the examples of this manual, there is an assumed message terminator at the end of each message. If the terminator needs to be shown, it is indicated as <NL> regardless of the actual terminator character.
SCPI Data Formats

All data programmed to or returned from the unit is ASCII. The data may be numerical or character string.

Numerical Data

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Data Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;NR1&gt;</td>
<td>Digits with an implied decimal point assumed at the right of the least-significant digit. Examples: 273 0273</td>
</tr>
<tr>
<td>&lt;NR2&gt;</td>
<td>Digits with an explicit decimal point. Example: 273. .0273</td>
</tr>
<tr>
<td>&lt;NR3&gt;</td>
<td>Digits with an explicit decimal point and an exponent. Example: 2.73E+2 273.0E-2</td>
</tr>
</tbody>
</table>

Listening Formats

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Data Form</th>
</tr>
</thead>
<tbody>

<td>&lt;NRf&gt;</td>
<td>Extended format that includes &lt;NR1&gt;, &lt;NR2&gt; and &lt;NR3&gt;. Examples: 273 273. 2.73E2</td>
</tr>
<tr>
<td>&lt;NRf+&gt;</td>
<td>Expanded decimal format that includes &lt;NRf&gt;, MIN and MAX. Examples: 273. 2.73E2 MAX. MIN and MAX are the minimum and maximum limit values that are implicit in the range specification for the parameter.</td>
</tr>
<tr>
<td>&lt;Bool&gt;</td>
<td>Boolean data. Either form 0</td>
</tr>
</tbody>
</table>

Suffixes and Multipliers

Some SCPI commands let you send engineering units as suffixes to extend numeric parameters. The following table lists the allowable suffixes and multipliers.

<table>
<thead>
<tr>
<th>Class</th>
<th>Suffix</th>
<th>Unit</th>
<th>Unit with Multiplier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current</td>
<td>A</td>
<td>Ampere</td>
<td>MA (milliampere)</td>
</tr>
<tr>
<td>Amplitude</td>
<td>V</td>
<td>Volt</td>
<td>MV (millivolt)</td>
</tr>
<tr>
<td>Time</td>
<td>S</td>
<td>second</td>
<td>MS (millisecond)</td>
</tr>
<tr>
<td></td>
<td>1E3</td>
<td>K</td>
<td>kilo</td>
</tr>
<tr>
<td></td>
<td>1E-3</td>
<td>M</td>
<td>milli</td>
</tr>
<tr>
<td></td>
<td>1E-6</td>
<td>U</td>
<td>micro</td>
</tr>
</tbody>
</table>

Character Data

For query statements, character strings may be returned in either of the forms shown in table 2-3, depending on the length of the returned string.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;CRD&gt;</td>
<td>Character Response Data. Permits the return of character strings.</td>
</tr>
<tr>
<td>&lt;AARD&gt;</td>
<td>Arbitrary ASCII Response Data. Permits the return of undelimited 7-bit ASCII. This data type has an implied message terminator.</td>
</tr>
<tr>
<td>&lt;SRD&gt;</td>
<td>String Response Data. Returns string parameters enclosed in double quotes.</td>
</tr>
</tbody>
</table>
Examples

Most examples given here are generic, without regard to the programming language or type of GPIB interface. Because SCPI commands are sent as ASCII output strings within the programming language statements, the SCPI syntax is independent of both programming language and interface. The examples are followed by sample program code written for an Agilent BASIC controlled GPIB interface.

Programming Voltage and Current

Note
The Agilent SAS responds simultaneously to both digital and analog programming inputs. If it is receiving an input over the GPIB and a corresponding input from the front panel (and from the analog programming port), the output will be the algebraic sum of the inputs. (Analog programming applies in Fixed mode only.)

The following statements program both voltage and current and return the actual output from the sense terminals:

OUTP OFF
Disable the output.
VOLT 55;CURR 2.5
Program the voltage and current.
VOLT?;CURR?
Read back the programmed levels.
OUTP ON
Enable the output.
MEAS:VOLT?;MEAS:CURR?
Read back the outputs from the sense terminals.

Programming Protection Circuits

This example programs the voltage and current, programs an overvoltage protection value, and turns on the overcurrent protection. It then reads back all the programmed values. Note the required use of the optional LEVel header in this example (see "Moving Among Subsystems" for more information).

VOLT:LEV 55;PROT 60
Program the voltage and overvoltage protection.
CURR:LEV 3;PROT:STAT ON
Program the current and overcurrent protection.
VOLT:LEV?;PROT?;:CURR:LEV?;PROT:STAT?
Read back the programmed values.

Programming Units in Auto-Parallel

Refer to “Auto-Parallel Programming Cautions” in chapter 4 before using Agilent SAS units in auto-parallel mode.

The following examples illustrate how to program a master unit and a slave unit that are connected in auto-parallel mode. The master unit is at address 705; the slave unit is at address 706. Refer to chapter 4 for connection information. Refer to chapter 7 for details about specific programming commands. The first example illustrates auto-parallel operation in Simulator mode.

1000 ! 2 Units in auto-parallel - Simulator Mode
1010 OUTPUT 705;"*RST"
1020 OUTPUT 706;"*RST"
1030 OUTPUT 705;"CURR:SAS:ISC 4;IMP 3;:VOLT:SAS:VOC 60;VMP 40"
1040 OUTPUT 706;"CURR:SAS:ISC 0;IMP 0;:VOLT:SAS:VOC 60;VMP 40"
1050 OUTPUT 705;"CURR:MODE:SAS"
1060 OUTPUT 706;"CURR:MODE:SAS"
1070 OUTPUT 705;"OUTP:STAT ON"
1080 OUTPUT 706;"OUTP:STAT ON"

Resets the master unit.
Resets the slave unit.
Program curve data for master unit
Program curve data for slave unit
Selects simulator mode for master unit.
Selects simulator mode for slave unit
Enables the output for master unit.
Enables the output for slave unit.
The following example illustrates auto-parallel operation in Table mode.

```
1000 ! 2 Units in auto-parallel - Table Mode
1010 OUTPUT 705;"*RST"
1020 OUTPUT 706;"*RST"
1030 OUTPUT 705;"MEM:TABL:SEL TABLE1"
1040 OUTPUT 705;"MEM:TABL:VOLT 0, 5, 10, 55, 60"
1050 OUTPUT 705;"MEM:TABL:CURR 4, 4, 3.5, 3, 2.5, 0"
1060 OUTPUT 705;"CURR:TABL:NAME TABLE1"

1080 OUTPUT 706;"MEM:TABL:VOLT 0, 5, 10, 55, 60, 999"
1090 OUTPUT 706;"MEM:TABL:CURR 4, 4, 3.5, 3, 2.5, 0, -999"
1060 OUTPUT 706;"CURR:TABL:NAME TABLE1"
1100 OUTPUT 705;"CURR:MODE:TABL;:OUTP:STAT ON"
1110 OUTPUT 706;"CURR:MODE:TABL;:OUTP:STAT ON"
```

Resets the master unit.
Resets the slave unit.
Selects a table for entering data for master unit
Enter voltage data for master unit
Enter current data for master unit
Activates the table for master unit
Selects a table for entering data for slave unit
Enter voltage data for slave unit
Enter current data for slave unit
Activates the table for slave unit
Enables the output for master unit.
Enables the output for slave unit.

### Changing Outputs by Trigger (applies in Fixed mode only)
If you do not program pending triggered levels, they default to the programmed (immediate) output levels. The following statements shows some basic trigger commands.

```
OUTP OFF
VOLT:LEV:IMM 55;TRIG 60
CURR:LEV:IMM 2.5;TRIG 3
VOLT:LEV:IMM?;TRIG?;:CURR:LEV:IMM?;TRIG?
OUTP ON
MEAS:VOLT?;CURR?
INIT;TRIG
INIT;*TRG
MEAS:VOLT?;CURR?
```

Disable the output.
Program the voltage to 55V and the triggered level to 60 V.
Program the current to 2.5 A and the triggered level to 3 A.
Check all the programmed values.
Enable the output.
Read back the immediate levels from the sense terminals.
Arm the trigger circuit and send a single trigger.
Same as above, except using a common command.
Read back the triggered levels from the sense terminals.

If you need to send two or more triggers, program the trigger circuit for continuous arming.

```
OUTP OFF
VOLT:LEV:IMM 60;TRIG 55
INIT:CONT ON
OUTP ON
TRIG
VOLT:TRIG 60;TRIG
INIT:CONT OFF
```

Disable the output.
Program the voltage to 60 V and the triggered level to 55 V.
Program the trigger circuit for continuous arming.
Enable the output to 60 V.
Trigger the output voltage to 55 V.
Set the pending trigger level to 60 V and send a single trigger.
Remove the continuous trigger arming.

### Saving and Recalling States
You can remotely save and recall operating states. See *SAV and *RCL in chapter 7 for more information.

**Note:** When you turn the Agilent SAS on, it automatically retrieves the state stored in location 0. When a unit is shipped, this location contains the factory defaults (see *RST in chapter 7).
Writing to the Display

You can include messages to the front panel LCD in your programs. The description of DISP:TEXT in chapter 7 shows the number and types of permitted display characters. In order to write to the display, you must first change it to text mode as shown in the following example:

DIS:MODE TEXT  Switch display to text mode.
RECALLED 2    Write “Recalled 2” to the display.
DIS:MODE NORM  Return display to its normal mode.

Programming Status

You can use status programming to make your program react to events within the Agilent SAS. Chapter 8 - Status Reporting explains the functions and bit configurations of all status registers. Refer to figure 8-1 in that chapter while examining the examples given here. Usually you will want the Agilent SAS to generate interrupts (assert SRQ) upon particular events. For this you must selectively enable the appropriate status register bits. The following examples allow the unit to assert SRQ under selected conditions.

STAT:OPER:ENAB 1280;PTR 1280;*SRE 128  Assert SRQ when the unit switches between CV and CC modes.
STAT:OPER:ENAB 1;PTR 1;NTR 1;*SRE 128  Assert SRQ when the unit enters or leaves calibration mode.
STAT:QUES 3;PTR 3;*SRE 128             Assert SRQ when the unit goes into overvoltage or overcurrent.
STAT:OPER:ENAB 1280;PTR 1280;          Assert SRQ under any event occurring in the operation or
:STAT:QUES 3;PTR 3;*SRE 136             questionable registers.

The following example illustrates how you can exercise program control without interrupts by reading specific registers.

STAT:OPER:1280;EVEN?               Enable only the CV and CC events and read their status.
STAT:OPER:ENAB 1313;PTR 1313;EVEN? Enable all conditions of the Operation Status register and read any events.
:STAT:QUES:ENAB?;EVEN?;:*ESE?;*ESR? Read which events are active and which events are enabled in the
                                          Operation, Questionable, and Standard Event status registers.

Note  The last query string can be handled without difficulty. However, should you request too many queries, the system may return a “Query DEADLOCKED” error (-430). In that case, break the long string into smaller parts.

Programming the Digital I/O Port

Digital control ports 1 and 2 are TTL outputs that can be programmed either high or low. Control port 3 can be programmed to be either a TTL input or a TTL output. Send a decimal parameter that translates into the desired straight binary code for these ports. (See DIG:DATA[:VAL] in chapter 7 for the port bit configurations.)

DIG:DATA 3  Set ports 1 and 2 high and make 3 another output port.
DIG:DATA 7  Set ports 1 and 2 high and make 3 an input port.
DIG:DATA?  Read back the present port configuration.

System Considerations

The remainder of this chapter addresses some system issues concerning programming. These are addressing and the use of the following types of GPIB system interfaces:

1. HP Vectra PC controller with Agilent 82335A GPIB Interface Command Library.
2. IBM PC controller with National Instruments GPIB-PCII Interface/Handler.
3. Agilent controller with Agilent BASIC Language System.

The example program at the end of this chapter is intended to show how some of the same Agilent SAS functions can be programmed for the Agilent BASIC interface.
Assigning the GPIB Address In Programs
The Agilent SAS address cannot be set remotely; it must be set from the front panel. Once the address is set, you can assign it inside programs. Refer to chapter 5 under “Setting the GPIB Address” for more information. The following example assumes that the GPIB select code is 7, the primary address is 6, and that the Agilent SAS address will be assigned to the variable @PS.

1000 !Stand-alone address. The unit will respond if it is set to 6
1010 PS=706 ! Statement for Agilent 82335A Interface
1010 ASSIGN @PS TO 706 ! Statement for Agilent BASIC Interface
1020 !Direct address. The unit will respond if it is set to 6, or 6.0
1030 PS=70600 ! Statement for Agilent 82335A Interface
1030 ASSIGN @PS TO 70600 ! Statement for Agilent BASIC Interface
1040 !Linked address 1. The unit responds if it is set to address .1 and is serially connected to a unit at direct address 6.0
1050 PS=706.01 ! Agilent 82335A Interface
1090 ASSIGN @PS TO 706.01 ! Agilent BASIC Interface

For systems using the National Instruments DOS driver, the address is specified in the software configuration program (IBCONFIG.EXE) and assigned a symbolic name. The address then is referenced only by this name within the application program (see the National Instruments GP-IB documentation).

Agilent 82335A Driver Considerations
For GW-BASIC programming, the GPIB library is implemented as a series of subroutine calls. To access these subroutines, your application program must include the header file SETUP.BAS, which is part of the DOS driver software.

SETUP.BAS starts at program line 5 and can run up to line 999. Your application programs must begin at line 1000. SETUP.BAS has built-in error checking routines that provide a method to check for GPIB errors during program execution. You can use the error-trapping code in these routines or write your own code using the same variables as used by SETUP.BAS. If there is no error-handling code in your program, undetected errors can cause unpredictable results.

National Instruments GP-IB Driver Considerations
Your program must include the National Instruments header file DECL.BAS. This contains the initialization code for the interface. Prior to running any applications programs, you must set up the interface with the configuration program (IBCONF.EXE).

Your application program will not include the unit’s symbolic name and GPIB address. These must be specified during configuration (when you run IBCONF.EXE). Note that the primary address range is from 0 to 30 but any secondary address must be specified in the address range of 96 to 126. The Agilent SAS expects a message termination on EOI or line feed, so set EOI w/last byte of Write. It is also recommended that you set Disable Auto Serial Polling.

All function calls return the status word IBSTA%, which contains a bit (ERR) that is set if the call results in an error. When ERR is set, an appropriate code is placed in variable IBERR%. Be sure to check IBSTA% after every function call. If it is not equal to zero, branch to an error handler that reads IBERR% to extract the specific error. If there is no error-handling code in your program, undetected errors can cause unpredictable results.

BASIC Considerations
The Agilent BASIC Programming Language provides access to GPIB functions at the operating system level. This makes it unnecessary to have the header files required in front of DOS applications programs. Also, you do not have to be concerned about controller "hangups" as long as your program includes a timeout statement. Because the Agilent SAS can be programmed to generate SRQ on errors, your program can use an SRQ service routine for decoding detected errors. The detectable errors are listed in appendix D.

Figure 6-3. Programming Agilent SAS Functions (continued)
Language Dictionary

Introduction

This section gives the syntax and parameters for all the IEEE 488.2 SCPI commands and the Common commands used by the Agilent SAS. It is assumed that you are familiar with the material in chapter 6 - Remote Programming. That chapter explains the terms, symbols, and syntactical structures used here and gives an introduction to programming. You should also be familiar with chapter 5 - Front Panel Operation in order to understand how the Agilent SAS functions.

The programming examples are simple applications of SCPI commands. Since SCPI syntax remains the same for all programming languages, the examples are generic.

Syntax definitions use the long form, but only short form headers (or "keywords") appear in the examples. If you have any concern that the meaning of a header in your program listing will not be obvious at some later time, then use the long form to help make your program self-documenting.

Parameters

Most commands require a parameter and all queries will return a parameter. The range for a parameter may vary according to the model of Agilent SAS. Parameters for all models are listed in Table 7-3.

Related Commands

Where appropriate, related commands or queries are included. These are listed either because they are directly related by function or because reading about them will clarify or enhance your understanding of the original command or query.

Order of Presentation

The dictionary is organized as follows:

- IEEE 488.2 common commands, in alphabetical order.
- Subsystem commands.

Common Commands

Common commands begin with an * and consist of three letters (command) or three letters and a ? (query). Common commands are defined by the IEEE 488.2 standard to perform some common interface functions. The Agilent SAS responds to the 13 required common commands that control status reporting, synchronization, and internal operations. The Agilent SAS also responds to five optional common commands controlling triggers, power-on conditions, and stored operating parameters.

Subsystem Commands

Subsystem commands are specific to Agilent SAS functions. They can be a single command or a group of commands. The groups are comprised of commands that extend one or more levels below the root. The description of subsystem commands follows the listing of the common commands.
Description Of Common Commands

Table 7-1 shows the common commands and queries. These commands are listed alphabetically in the dictionary. If a command has a corresponding query that simply returns the data or status specified by the command, then both command and query are included under the explanation for the command. If a query does not have a corresponding command or is functionally different from the command, then the query is listed separately. The description of each common command or query specifies any status registers affected. In order to make use of this information, you must refer to "Chapter 4 - Status Reporting", which explains how to read specific register bits and use the information that they return.

*CLS

Meaning and Type
Clear Status  Device Status

Description
This command causes the following actions (see "Chapter 4 - Status Reporting" for descriptions of all registers):
- Clears the Standard Event Status, Operation Status Event, Questionable Status Event, and Status Byte registers.
- Clears the Error Queue.
- If *CLS immediately follows a program message terminator (<NL>), then the output queue and the MAV bit are also cleared.

Command Syntax  *CLS
Parameters       (None)
Query Syntax     (None)

*ESE

Meaning and Type
Event Status Enable  Device Status

Description
This command programs the Standard Event Status Enable register bits. The programming determines which events of the Standard Event Status Event register (see *ESR?) are allowed to set the ESB (Event Summary Bit) of the Status Byte register. A "1" in the bit position enables the corresponding event. All of the enabled events of the Standard Event Status Event register are logically ORed to cause the Event Summary Bit (ESB) of the Status Byte register to be set. See chapter 4 - "Status Reporting" for descriptions of all three registers.

Bit Configuration of Standard Event Status Enable Register

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

CME = Command error; DDE = Device-dependent error; EXE = Execution error; OPC = Operation complete; PON = Power-on; QYE = Query error.
If PSC is programmed to 0, the *ESE register bits are stored in nonvolatile memory. The nonvolatile memory has a finite maximum number of write cycles (see Supplemental Characteristics in appendix A). Programs that repeatedly write to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.

**Command Syntax**  
*ESE <NR>  

**Parameters**  
0 to 255

**Power On Value**  
(See *PSC)

**Suffix**  
(None)

**Example**  
*ESE 129

**Query Syntax**  
*ESE?

**Returned Parameters**  
<NR> (Register value)

**Related Commands**  
*ESR? *PSC *STB?

### *ESR?*

#### Meaning and Type

*Event Status Register*  
Device Status

#### Description

This query reads the Standard Event Status Event register. Reading the register clears it. The bit configuration of this register is the same as the Standard Event Status Enable register (*ESE*). See "Chapter 4 - Status Reporting" for a detailed explanation of this register.

**Query Syntax**  
*ESR?

**Parameters**  
(None)

**Returned Parameters**  
<NR> (Register binary value)

**Related Commands**  
*CLS *ESE *ESE? *OPC

### *IDN?*

#### Identification Query

#### Meaning and Type

*Identification*  
System Interface

#### Description

This query requests the Agilent SAS to identify itself. It returns a string composed of four fields separated by commas.

**Query Syntax**  
*IDN?

**Returned Parameters**  
<AARD>

**Field**  
Agilent Technologies  
EnnnnB  
USnnnnnnnn  
<RR>.xx.xx

**Information**  
Manufacturer  
6-character model number  
10-character serial number or 0  
Revision levels of firmware

**Example**  
AGILENT TECHNOLOGIES,E4350B,0,A.00.01

**Related Commands**  
(None)
*OPC

Meaning and Type
Operation Complete  Device Status

Description
This command causes the interface to set the OPC bit (bit 0) of the Standard Event Status register when the Agilent SAS has completed all pending operations. (See *ESE for the bit configuration of the Standard Event Status register.) Pending operations are complete when:

- All commands sent before *OPC have been executed. This includes overlapped commands. Most commands are sequential and are completed before the next command is executed. Overlapped commands are executed in parallel with other commands. Commands that affect output voltage, current or state, relays, and trigger actions are overlapped with subsequent commands sent to the Agilent SAS.
- Any change in the output level caused by previous commands has been completed.
- All triggers are completed.

*OPC does not prevent processing of subsequent commands but Bit 0 will not be set until all pending operations are completed.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>*OPC</td>
<td>(None)</td>
<td>(None)</td>
<td>*OPC?  *ESE</td>
</tr>
</tbody>
</table>

*OPC?

Meaning and Type
Operation Complete  Device Status

Description
This query causes the interface to place an ASCII "1" in the Output Queue when all pending operations are completed. Pending operations are as defined for the *OPC command. Unlike *OPC, *OPC? prevents processing of all subsequent commands. *OPC? is intended to be used at the end of a command line so that the application program can then monitor the bus for data until it receives the "1" from the power module Output Queue.

**CAUTION**
Do not follow *OPC? with *TRG or GPIB bus triggers. Since triggers sent after *OPC? will not execute, this will prevent the unit from accepting further commands. If this occurs, the only programmable way to restore operation is by sending the Agilent SAS a GPIB DCL (Device Clear).

<table>

*PSC

**Meaning and Type**

*Power-on Status Clear* Device Initialization

**Description**

This command controls the automatic clearing at power turn-on of the Service Request Enable register and the Standard Event Status Enable register. The setting of the *PSC* command is stored in non-volatile memory.

If the command parameter = 1, then the above registers are cleared at power turn-on. If the command parameter = 0, then the above registers are not cleared at power turn-on but are programmed to their last state prior to power turn on. This is the most common application for *PSC* and enables the power module to generate an SRQ (Service Request) at power on.

*PSC* writes to nonvolatile memory. If *PSC* is programmed to 0, then the *ESE* and *SRE* commands also write to nonvolatile memory. The nonvolatile memory has a finite maximum number of write cycles (see Supplemental Characteristics in appendix A). Programs that repeatedly write to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.

---

**Command Syntax**

*PSC* <bool>

**Parameters**

0 | 1 | OFF | ON

**Example**

*PSC* 0  *PSC* 1

**Query Syntax**

*PSC?*

**Returned Parameters**

<NR1> 0 | 1

**Related Commands**

*ESE* *SRE* *RCL*

---

*RCL*

**Meaning and Type**

*Recall* Device State

---

**WARNING**

Recalling a previously stored state may place hazardous voltage at the Agilent SAS output.

---

**Description**

This command restores the Agilent SAS to a state that was previously stored in memory with a *SAV* command to the specified location. The following states are recalled:

Sending *RCL* also does the following:

- Forces an ABORt command before resetting any parameters (this cancels any uncompleted trigger actions).
- Disables the calibration function by setting CAL:STATe to OFF.
- Sets display functions as follows:
  - [:WIND]:STATE to ON.
  - [:WIND]:MODE to NORMAL.
  - [:WIND]:TEXT to ‘ ’.
- Sets INIT:CONT to OFF.
- Sets TRIG:SOUR to BUS.
- Resets the Agilent SAS to FIXed mode (CURR:MODE:FIX)

At power turn-on, the Agilent SAS normally is returned to the factory defined turn-on state (see *RST*). However, it also may turn on to the state stored in location 0 (see chapter 5 under *Turn-On Condition*).
Command Syntax  *RCL <NRf>
Parameters  0 | 1 | 2 | 3
Example  *RCL 3
Query Syntax  (None)
Related Commands  *PSC  *RST  *SAV

*RST

Meaning and Type
Reset  Device State

Description
This command resets the Agilent SAS to a factory-defined state as defined below. *RST also forces an ABORt command. If Simulator or Table mode had previously been programmed, the operation of the unit returns to Fixed mode. Simulator mode settings revert to the factory default values, and no tables are selected.

<table>

</tbody>
</table>

Model-dependent value. See Table 7-3.

Command Syntax  *SAV
Parameters (None)
Query Syntax (None)
Related Commands  *PSC  *SAV

*SAV

Meaning and Type
SAVE  Device State

Description
This command only applies in Fixed operating mode. It saves the present state of the Agilent SAS to the specified location in non-volatile memory. Up to four states can be stored. Under certain conditions (see Turn-On Conditions in chapter 5), location 0 may hold the device state that is automatically recalled at power turn-on. Simulator and Table mode states cannot be saved by this command. The following Agilent SAS parameters are stored by *SAV:

CURR:PROT:STAT  OUTP: PROT: DEL  VOLT[:LEV][;IMM]
The Agilent SAS uses nonvolatile memory for recording register states. Programs that repeatedly use *SAV for recalling states cause frequent write cycles to the memory and can eventually exceed the maximum number of write cycles and may cause the memory to fail (see Supplemental Characteristics in appendix A).

**Command Syntax**

*SAV <NRf>

**Parameters**

0|1|2|3

**Example**

SAV 3

**Query Syntax**

(None)

**Related Commands**

*RCL  *RST

---

**SRE**

**Meaning and Type**

Service Request Enable  Device Interface

**Description**

This command sets the condition of the Service Request Enable Register. This register determines which bits from the Status Byte Register (see *STB for its bit configuration) are allowed to set the Master Status Summary (MSS) bit and the Request for Service (RQS) summary bit. A 1 in any Service Request Enable Register bit position enables the corresponding Status Byte Register bit and all such enabled bits then are logically ORed to cause Bit 6 of the Status Byte Register to be set. See “Chapter 4 - Status Reporting” for more details concerning this process.

When the controller conducts a serial poll in response to SRQ, the RQS bit is cleared, but the MSS bit is not. When *SRE is cleared (by programming it with 0), the Agilent SAS cannot generate an SRQ to the controller.

---

**CAUTION**

If PSC is programmed to 0, the *SRE register bits are stored in nonvolatile memory. The nonvolatile memory has a finite maximum number of write cycles (see Supplemental Characteristics in appendix A). Programs that repeatedly write to nonvolatile memory can eventually exceed the maximum number of write cycles and may cause the memory to fail.

**Command Syntax**

*SRE <NRf>

**Parameters**

0-to 255

**Default Value**

(See *PSC)

**Example**

*SRE 20

**Query Syntax**

*SRE?

**Returned Parameters**

<NR1> (Register binary value)

**Related Commands**

*ESE  *ESR  *PSC

---

**STB?**

**Meaning and Type**

Status Byte  Device Status

**Description**

This query reads the Status Byte register, which contains the status summary bits and the Output Queue MAV bit. Reading the Status Byte register does not clear it. The input summary bits are cleared when the appropriate event registers are read (see “Chapter 4 - Status Reporting” for more information). The MAV bit is cleared at power on or by *CLS.

A serial poll also returns the value of the Status Byte register, except that bit 6 returns a Request for Service (RQS) instead of a Master Status Summary (MSS). A serial poll clears RQS, but not MSS. When MSS is set, it indicates that the Agilent SAS has one or more reasons for requesting service.
Bit Configuration of Status Byte Register

<table>

Description Of Subsystem Commands

Table 7-2 is a tree diagram of the subsystem commands. Commands followed by a question mark (?) take only the query form. Except as noted in the syntax descriptions, all other commands take both the command and query form. The commands are listed in alphabetical order and the commands within each subsystem are grouped alphabetically under the subsystem.

This summary lists all Agilent SAS subsystem commands in alphabetical order, followed by all common commands in alphabetical order. See Table 7-3 for the command parameters accepted by each Agilent SAS model.

Calibration Commands

See appendix B.

Display Subsystem

This subsystem controls the state and output of the alphanumeric portion of the display.

DISP

Enables or disables the display. When disabled, the display characters are blank. The annunciators are not affected by this command.

Command Syntax: DISPLAY[:WINDow][:STATe] <bool>
Parameters: 0 | 1 | OFF | ON
*RST Value: ON
Examples: DISPLAY ON DISPLAY:STATE ON
Query Syntax: DISPLAY[:WINDow][:STATe]?
Returned Parameters: <NR1> 0 or 1
Related Commands: DISP:MODE DISP:TEXT

DISP:MODE

Switches the display between its normal metering mode and a mode in which it displays text sent by the user.

Command Syntax: DISPLAY[:WINDow]:MODE <CRD>
Parameters: NORMal | TEXT
*RST Value: NORM
Examples: DISPLAY:MODE NORM DISPLAY:MODE NORMAL
Query Syntax: DISPLAY[:WINDow]:MODE?
Returned Parameters: <CRD> NORMAL or TEXT
Related Commands: DISP DISP:TEXT
**DISP:TEXT**

Sends character strings to the display when the display mode is TEXT. The LCD display has the following character set:

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uppercase letters</td>
<td>A through Z (Case-sensitive entry)</td>
</tr>
<tr>
<td>digits</td>
<td>0 through 9</td>
</tr>
<tr>
<td>punctuation</td>
<td>_</td>
</tr>
<tr>
<td>blank space</td>
<td></td>
</tr>
</tbody>
</table>

A display is capable of showing up to 12 characters. However, the three punctuation characters do not count toward the 12-character limit when they are preceded by an alphanumeric character. When punctuation characters are included, then the maximum number of characters (alphanumeric + punctuation) that can be displayed is 15. If it exceeds the display capacity, a message will be truncated to fit and no error message will be generated. If any character in the message is not a member of the above character set, the character will be displayed as a starburst (all 16 segments of the character are lit).

**Note**

IEEE Standard Digital Interface for Programmable Instrumentation requires that a string be enclosed in either single ('') or double (" ") quotes.

---

**Measure Subsystem**

Measurement commands measure the output voltage and current.

**MEAS:CURR?**  
**MEAS:VOLT?**

These queries return the voltage and current measured at the Agilent SAS's sense terminals.

<table>
<thead>
<tr>

<td></td>
<td>&lt;NR3&gt;</td>
</tr>
</tbody>
</table>
Memory Subsystem
This subsystem manages the instrument’s data table memory.

MEM:COPY:TABL
This command copies the table that was selected with MEM:TABL:SEL to non-volatile memory. You can use the same name or a different name. Names cannot be longer than 12 alphanumeric characters and must start with an alpha character. A maximum of 30 tables can be stored in non-volatile memory. Non-volatile memory has only 3,500 table points available to be shared among all tables. Tables larger than 3,500 points cannot be copied.

Command Syntax:  MEM:CY:TB: <NAME>
Parameters:  a valid table name
Examples:  MEM:COPY:TABL curve1

MEM:DEL:ALL
MEM:DEL[:NAME]
These commands delete all, or the specified user-defined table in both volatile and non-volatile memory. Note that MEM:DEL:ALL does not delete any tables if a table has been activated with the SOURCE:CURRent:TABL command.

Command Syntax:  MEM:DEL:ALL
MEM:DEL[:NAME] <NAME>
Parameters:  a valid table name
Examples:  MEM:DEL:ALL  MEM:DEL:NAME curve1

MEM:TABL:SEL
This command creates a new table to be programmed with a list of voltage and current points. Table names cannot be longer than 12 alphanumeric characters and must start with an alpha character. This command is also used to select an existing table in volatile memory to be copied into non-volatile memory using MEM:COPY:TABL. If you send this command without specifying a table name, it will de-select any selected table.

Command Syntax:  MEM:TBSEL [NAME]
Parameters:  a valid table name
Examples:  MEM:TABL:SEL  MEM:TABL:SEL curve1

MEM:TABL:CURR
MEM:TABL:VOLT
These commands program a list of current or voltage points for a new table. A table must have at least 3 points. A maximum of 100 comma-separated points may be entered each time the commands are used. Repeatedly sending this command will append additional points to the end of the table, up to a maximum of 4000 points. A maximum of 30 tables can be stored in volatile memory. Volatile memory has 30,000 table points available to be shared among all tables.

If you are programming a slave unit that is paralleled to a master unit, you must send the same values to the slave unit. However, you must append a -999 to the end of the current string and a +999 to the end of the voltage string. These values configure the unit as a slave.

Command Syntax:  MEM:TB:CURR [:MAG]: <NAME>
MEM:TB:VOLT [:MAG]: <NAME>
Parameters:  0 to maximum current or voltage rating
            (current values must be entered in equal or in descending order; voltage values must be entered in ascending order)
Default Value:  0
Examples:  MEM:TABL:CURR 7,8,7,7,5,7,6,5,5,4,3,2,1
            MEM:TABL:CURR 7,8,7,7,5,7,6,5,5,4,3,2,1,-999 (paralleled slave unit)
            MEM:TABL:VOLT 5,35,45,50,52,54,56,57,58,59
            MEM:TABL:VOLT 5,35,45,50,52,54,56,57,58,59,999 (paralleled slave unit)
MEM:TABL:CURR:POIN?
MEM:TABL:VOLT:POIN?

These commands return the number of current or voltage points in the active table.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Output Subsystem

**Output** commands control the Agilent SAS's voltage and current outputs and an optional output relay. **Source** commands program the actual voltage, current, and protection functions.

**OUTP**

This command enables or disables the Agilent SAS output. The state of a disabled output is a condition of zero output voltage and a model-dependent minimum source current (see Table 7-3). The query form returns the output state.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>OUTPut[:STATE] &lt;bool&gt;</th>
</tr>
</thead>
<tbody>

<td>OUTPut[:STATE]?</td>
</tr>
<tr>
<td>Returned Parameters</td>
<td>&lt;NR1&gt; 0 or 1</td>
</tr>
<tr>
<td>Related Commands</td>
<td>*RST</td>
</tr>
</tbody>
</table>

**OUTP:PROT:CLE**

This command clears any OV (overvoltage), OC (overcurrent), OT (overtemperature), or RI (remote inhibit) protection features. After this command, the output is restored to the state it was in before the protection feature occurred.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>OUTPut:PROTection:CLEar</th>

<tr>
<td>Parameters</td>
<td>(None)</td>
</tr>
<tr>
<td>Query Syntax</td>
<td>(None)</td>
</tr>
<tr>
<td>Examples</td>
<td>OUTP:PROT:CLE</td>
</tr>
</tbody>
</table>
OUTP:PROT:DEL

This command only applies in Fixed mode. It sets the time in seconds between the programming of an output change that produces a CV, CC, or UNREG condition and the recording of that condition by the Status Operation Condition register. The delay prevents the momentary changes in Agilent SAS status that can occur during reprogramming from being registered as events by the status subsystem. Since the delay applies to CC status, it also delays the OCP (Fixed mode overcurrent protection) feature. The OVP (overvoltage protection) and the OC (overcurrent level) is not affected by this delay.

Command Syntax

```
OUTPut:PROTection:DELay <NRf>
```

Parameters

- **0** to **32,767**
- **MIN**
- **MAX**

Units

- **seconds**

*RST Value

- **0**

Examples

```
OUTPUT:PROTECTION:DELAY 75E-1
```

Query Syntax

```
OUTPut:PROTection:DELay?
```

Returned Parameters

- `<NR3>`

Related Commands

* RST  * RCL  * SAV  CURR:PROT:STAT

[SOUR:]CURR

These commands only apply in Fixed mode. They set the immediate current level or the pending triggered current level of the Agilent SAS. The immediate level is the current programmed for the output terminals. The pending triggered level is a stored current value that is transferred to the output terminals when a trigger occurs. A pending triggered level is unaffected by subsequent CURR commands and remains in effect until the trigger subsystem receives a trigger or an ABORt command is given. If there is no pending CURR:TRIG level, then the query form returns the CURR level. In order for CURR:TRIG to be executed, the trigger subsystem must be initiated (see INITiate).

Command Syntax

```
[SOURce]:CURRent[:LEVEL][:IMMediate][:AMPLitude] <NRf+>
[SOURce][:CURRent][:LEVEL]:TRIGgered [:AMPLitude] <NRf+>
```

Parameters

Table 7-3

Default Suffix

- **A**

*RST Value

- Table 7-3

Examples

```
CURR 200 MA  CURRENT:LEVEL 200 MA
CURR:TRIG 20  CURRENT:LEVEL:TRIGGERED 20
```

Query Syntax

```
[SOURce]:CURRent[:LEVEL] [:IMMediate][:AMPLitude]?
[SOURce]:CURRent[:LEVEL] [:IMMediate][:AMPLitude]?  MAX
[SOURce]:CURRent[:LEVEL] [:IMMediate][:AMPLitude]?  MIN
[SOURce]:CURRent[:LEVEL]:TRIGgered [:AMPLitude]?
[SOURce]:CURRent[:LEVEL]:TRIGgered [:AMPLitude]?  MAX
[SOURce]:CURRent[:LEVEL]:TRIGgered [:AMPLitude]?  MIN
```

Returned Parameters

- `<NR3>`
- CURR? and CURR:TRIG? return presently programmed immediate and triggered levels. If not triggered level is programmed, both returned values are the same.
- CURR? MAX and CURR? MIN return the maximum and minimum programmable immediate current levels.
- CURR:TRIG? MAX and CURR:TRIG? MIN return the maximum and minimum programmable triggered current levels.

Related Commands

For CURR  * SAV  * RCL  * RST
For CURR:TRIG  ABOR  CURR  * RST
[SOUR:]CURRent:MODE

This command selects the operating mode of the Agilent SAS. The choices are:

**FIXed**

In Fixed mode, the output is a fixed rectangular I-V characteristic. The output capacitance is <100 nF on the Agilent E4350B and <50 nF on the Agilent E4351B, which optimizes the unit as a constant current source. To use the unit as a low-impedance constant voltage source, you can add an external output capacitor if desired, the value of which should not exceed 2,000 µF. Fixed mode is the power-on default mode.

**SASimulator**

Simulator mode uses an exponential model to approximate the I-V curve. It is programmed in terms of its open circuit voltage (Voc), short circuit current (Isc), voltage point (Vmp), and current point (Imp) at approximately the peak power point. All of these parameters are set using separate SCPI commands (see chapter 1 for more information about Simulator mode).

**TABLe**

Table mode sets the output characteristics by a user-defined table of voltage/current points. A curve is generated by connecting the points by straight lines. Therefore, the more points that are provided, the more the connected points will resemble a curve.

- **Maximum number of tables:** 30 volatile and 30 nonvolatile
- **Maximum table size (per table):** 4,000 points
- **Maximum non-volatile table points available for all tables:** 3,500 points
- **Maximum volatile table points available for all tables:** 30,000 points

Tables are programmed using the MEMory commands as previously discussed.

**Command Syntax**

[SOURce]:CURRent:MODE <mode>

[SOUR:]CURR:PROT

This command sets an overcurrent protection level. This is a hardware protection function similar to overvoltage protection. Although always active, its primary use is in Simulator and Table modes, which do not have the constant-current OCP protection that is available in Fixed mode. When activated, both front panel OV and OC annunciators are lit. Note that the OUT:PROT:DEL command does not apply to this hardware overcurrent protection function.

**Command Syntax**

[SOURce]:CURRent:PROTection[:LEVel] <level>

</tbody>
</table>

[SOUR:]CURR:PROT:STAT

This command is active in Fixed mode only. It enables or disables the Agilent SAS overcurrent protection (OCP) function. If the overcurrent protection function is enabled and the Agilent SAS goes into constant-current operating mode, then the output is disabled and the Questionable Condition status register OC bit is set (see chapter 8 for more information). An overcurrent condition can be cleared with the OUTP:PROT:CLE command after the cause of the condition is removed.

**Command Syntax**

[SOURce]:CURRent:PROTection:STATe <bool>

</table>
[SOUR:]CURRE:CURRent:SAS:ISC
This command sets the short-circuit current for the Simulator mode. If you are programming a slave unit that is paralleled to a master unit, you must set $I_{SC}$ and $I_{MP}$ to zero (0). This configures the unit to act as a slave.

Command Syntax
[SOURce]:CURRent:SASimulator:ISC <NRf>

Parameter for ISC
0 to 8A for Agilent E4350B (0 configures the unit as a slave)
0 to 4A for Agilent E4351B (0 configures the unit as a slave)

*RST Value
0
Examples
CURR:SAS:ISC 5
CURR:SAS:ISC 5;VOLT:SAS:VOC 60;VMP 50
CURR:SAS:ISC 0;VOLT:SAS:VOC 60;VMP 50 (auto paralleled slave)

Query Syntax
CURR:SAS:ISC?

Returned Parameters <NRI>

[SOUR:]CURRE:CURRent:SAS:IMP
This command sets the current at the peak power point of the Simulator mode. If you are programming a slave unit that is paralleled to a master unit, you must set $I_{MP}$ and $I_{SC}$ to zero (0). This configures the unit to act as a slave.

Command Syntax
[SOURce]:CURRent:SASimulator:IMP <NRf>

Parameter for IMP
≤ ISC (0 configures the unit as a slave)

*RST Value
0.8 X 8.16A for Agilent E4350B
0.8 X 4.08A for Agilent E4351B

Examples
CURR:SAS:IMP 4
CURR:SAS:ISC 5;VOLT:SAS:VOC 60;VMP 50
CURR:SAS:ISC 0;VOLT:SAS:VOC 60;VMP 50 (auto paralleled slave)

Query Syntax
CURR:SAS:IMP?

Returned Parameters <NRI>

[SOUR:]CURRE:CURRent:TABLe:NAME
This command activates a user-defined table when the unit is operating in Table mode. If the unit is not in Table mode, the specified table becomes the active table when Table mode is invoked. If you send this command with a space as the table name, it de-selects the active table. This allows the MEMory:DELete:ALL command to delete all tables in memory.

Command Syntax
[SOURce]:CURRent:TABLe:NAME <name>

Parameter
a valid table name or a space

Examples
CURR:TABL:NAME curve1

Query Syntax
CURR:TABL:NAME?

Returned Parameters <CRD>

[SOUR:]CURRE:CURRent:TABLe:OFFS
This command adds a current offset when operating in Table mode.

Command Syntax
[SOURce]:CURRent:TABLe:OFFSet <NRf>

Parameter
0 to Imax

*RST Value
0

Examples
CURR:TABL:OFFSet 4

Query Syntax
CURR:TABL:OFFSet?

Returned Parameters <NRI>

[SOUR:]DIG:DATA
This command sets and reads the Agilent SAS digital control port when that port is configured for Digital I/O operation. Configuring of the port is done via an internal jumper (see Appendix D). The port has three signal pins and a digital ground pin. Pins 1 and 2 are output pins controlled by bits 0 and 1. Pin 3 is controlled by bit 3 and can be programmed to serve either as an input or an output. Pin 4 is the digital ground.

Language Dictionary 77
Bit position 2 normally serves as an output. To change it to an input, it must first be programmed high. The DIG:DATA? query returns the last programmed value in bits 0 and 1 and the value read at pin 3 in bit 2. The bits are turned on and off in straight binary code as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Configuration</th>
<th>Pin Configuration 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 0 0 0</td>
<td>Lo Lo Output Gnd</td>
</tr>
<tr>
<td>1</td>
<td>1 0 0 0</td>
<td>Hi Lo Output Gnd</td>
</tr>
<tr>
<td>2</td>
<td>0 1 0 0</td>
<td>Lo Hi Output Gnd</td>
</tr>
<tr>
<td>3</td>
<td>1 1 0 0</td>
<td>Hi Hi Output Gnd</td>
</tr>
</tbody>
</table>

1 Pins 1 and 2 are always outputs

**Command Syntax**

Parameters 0 to 7  
*RST Value 0  
Examples DIG:DATA 7 DIG:DATA:VALUE 7  
Query Syntax [SOURce]:DIGit:DATA?  
Returned Parameters <NRf> Values from 0 to 7  
Related Commands *RST *RCL *SAV

**[SOUR:]VOLT**  
**[SOUR:]VOLT:TRIG**

These commands set the immediate voltage level or the pending triggered voltage level of the Agilent SAS. The immediate level is the voltage programmed for the output terminals. The pending triggered level is a stored voltage value that is transferred to the output terminals when a trigger occurs. A pending triggered level is unaffected by subsequent VOLT commands and remains in effect until the trigger subsystem receives a trigger or an ABORT command is given. If there is no pending VOLT:TRIG level, then the query form returns the VOLT level. In order for VOLT:TRIG to be executed, the trigger subsystem must be initiated (see INITiate).

**Command Syntax**  
[SOURce]:VOLTage[:LEVel][:IMMediate][:AMPLitude] <NRf+>  
Parameters Table 7-3  
Default Suffix V  
*RST Value  
Examples VOLT 200 MA VOLTAGE:LEVEL 200 MA  
VOLTAGE:LEVEL:IMMEDIATE:AMPLITUDE 2.5  
VOLT:TRIG 20 VOLTAGE:LEVEL:TRIGGERED 20  
Query Syntax [SOURce]:VOLTage[:LEVel][:IMMediate][:AMPLitude]?  
[SOURce]:VOLTage[:LEVel][:IMMediate][:AMPLitude]? MAX  
[SOURce]:VOLTage[:LEVel][:IMMediate][:AMPLitude]? MIN  
[SOURce]:VOLTage[:LEVel]:TRIGgered[:AMPLitude]?  
[SOURce]:VOLTage[:LEVel]:TRIGgered[:AMPLitude]? MAX  
[SOURce]:VOLTage[:LEVel]:TRIGgered[:AMPLitude]? MIN  
Returned Parameters <NR3> VOLT? and VOLT:TRIG? return presently programmed immediate and triggered levels. If not triggered level is programmed, both returned values are the same.  
VOLT? MAX and VOLT? MIN return the maximum and minimum programmable immediate voltage levels.  
VOLT:TRIG? MAX and VOLT:TRIG? MIN return the maximum and minimum programmable triggered voltage levels.  
Related Commands For VOLT *SAV *RCL *RST  
For VOLT:TRIG ABOR VOLT *RST

"Language Dictionary"
This command sets the overvoltage protection (OVP) level of the Agilent SAS. If the output voltage exceeds the OVP level, then the Agilent SAS output is disabled and the Questionable Condition status register OV bit is set (see chapter 8 for more information). An overvoltage condition can be cleared with the OUTP:PROT:CLE command after the condition that caused the OVP trip is removed. The OVP always trips with zero delay and is unaffected by the OUTP:PROT:DEL command.

**Command Syntax**

```
[SOURce]:VOLTage:PROTection[:LEVel] <NRf+>
```

**Parameters**

Table 7-3

**Default Suffix**

V

**RST Value**

MAX

**Examples**

VOLT:PROT 21.5  VOLT:PROT:LEV MAX
VOLTAGE:PROTECTION:LEVEL 145E-1

**Query Syntax**

```
[SOURce]:VOLTage:PROTection[:LEVel]?
```

**Returned Parameters**

VOLT:PROT? returns presently programmed OVP level.
VOLT:PROT? MAX and VOLT:PROT? MIN return the maximum and minimum programmable OVP levels.

**Related Commands**

OUTP:PROT:CLE  *RST  *SAV  *RCL

This command sets the open circuit voltage in Simulator mode. If you are programming a slave unit that is paralleled to a master unit, you must set the same Voc value to the master and the slave unit.

**Command Syntax**

```
[SOURce]:VOLTage:SASimulator:VOC <NRf>
```

**Parameters**

0 to 65V for Agilent E4350B
0 to 130V for Agilent E4351B

**RST Value**

Vmax

**Examples**

VOLT:SAS:VOC 60

**Query Syntax**

```
[SOURce]:VOLTage:SASimulator:VOC?
```

**Returned Parameters**

VOLT:SAS:VOC?

**Related Commands**

VOLT:SAS:VMP

This command sets the voltage at the peak power point in Simulator mode. If you are programming a slave unit that is paralleled to a master unit, you must set the same Vmp value to the master and the slave unit.

**Command Syntax**

```
[SOURce]:VOLTage:SASimulator:VMP <NRf>
```

**Parameters**

≤ VOC

**RST Value**

0.8 X 61.5V for Agilent E4350B
0.8 X 123V for Agilent E4351B

**Examples**

VOLT:SAS:VMP 50

**Query Syntax**

```
[SOURce]:VOLTage:SASimulator:VMP?
```

**Returned Parameters**

VOLT:SAS:VMP?

**Related Commands**

VOLT:SAS:VOC
[SOUR:]VOLT:TABL:OFFS

This command adds a voltage offset when operating in table mode.

Command Syntax  
[SOURce]:VOLTage:TABLE:OFFSet <NRf>

Parameter  
0 to VMAX

*RST Value 0

Examples  
VOLT:TABL:OFFSet 4

Query Syntax  
VOLT:TABL:OFFS?

Returned Parameters  <NRi>

Status Subsystem

This subsystem programs the Agilent SAS status registers. The Agilent SAS has three groups of status registers; 
**Operation**, **Questionable**, and **Standard Event**. The Standard Event group is programmed with Common commands as described in “Chapter 4 - Status Reporting”. The Operation and Questionable status groups each consist of the Condition, Enable, and Event registers and the NTR and PTR filters. See chapter 4 for more information about these registers.

Status Operation Registers

<table>
<thead>
<tr>

CAL = Interface is computing new calibration constants; CC = The power module is in constant current mode. CV = The power module is in constant voltage mode; NU = (Not used); WTG = Interface is waiting for a trigger.

STAT:OPER?

This query returns the value of the Operation Event register. The Event register is a read-only register which holds (latches) all events that are passed by the Operation NTR and/or PTR filter. Reading the Operation Event register clears it.

<table>
<thead>
<tr>
<th>Query Syntax</th>
<th>STATUS:OPERtion[:EVENT]?</th>

</tr>
<tr>
<td>Related Commands</td>
<td>STATUS:OPERIOTION:CONDITION?</td>
</tr>
</tbody>
</table>
**STAT:OPER:ENAB**

This command and its query set and read the value of the Operational Enable register. This register is a mask for enabling specific bits from the Operation Event register to set the operation summary bit (OPER) of the Status Byte register. This bit (bit 7) is the logical OR of all the Operational Event register bits that are enabled by the Status Operation Enable register.

```
Command Syntax     =status:oper:enable <nr1>
Parameters         =0 to 32767
Suffix             =(none)
Default Value      =0
Examples           =stat:oper:enab 1312    stat:oper:enab 1
Query Syntax       =status:oper:enable?
Returned Parameters=<nr1> (Register value)
Related Commands   =stat:oper:even
```

**STAT:OPER NTR/PTR Commands**

These commands set or read the value of the Operation NTR (Negative-Transition) and PTR (Positive-Transition) registers. These registers serve as polarity filters between the Operation Enable and Operation Event registers to cause the following actions:

- When a bit in the Operation NTR register is set to 1, then a 1-to-0 transition of the corresponding bit in the Operation Condition register causes that bit in the Operation Event register to be set.
- When a bit of the Operation PTR register is set to 1, then a 0-to-1 transition of the corresponding bit in the Operation Condition register causes that bit in the Operation Event register to be set.
- If the same bits in both NTR and PTR registers are set to 1, then any transition of that bit at the Operation Condition register sets the corresponding bit in the Operation Event register.
- If the same bits in both NTR and PTR registers are set to 0, then no transition of that bit at the Operation Condition register can set the corresponding bit in the Operation Event register.

**Note**

Setting a bit in the value of the PTR or NTR filter can of itself generate positive or negative events in the corresponding Operation Event register.

```
Command Syntax     =status:operation:ntransition <nr1>
status:operation:ptransition <nr1>
Parameters         =0 to 32767
Suffix             =(none)
Default Value      =0
Examples           =stat:oper:ntr 32    stat:oper:ptr 1312
Query Syntax       =status:oper:ntr?    status:oper:ptr?
Returned Parameters=<nr1> (Register value)
Related Commands   =stat:oper:enab
```

**STAT:PRES**

This command sets all defined bits in the Status Subsystem PTR registers and clears all bits in the subsystem NTR and Enable registers. STAT:OPER:PTR is set to 1313 and STAT:QUES:PTR is set to 1555.

```
Command Syntax     =status:preset
Parameters         =(none)
Examples           =status:pres    status:preset
Query Syntax       =(none)
Related Commands   =(none)
```

</table>

NU = (Not used); OC = Overcurrent protection circuit (OCP) or hardware overcurrent level (OC) has tripped.
OT = Overtemperature status condition exists; OV = Overvoltage protection circuit has tripped.
RI = Remote inhibit is active; UNR = Agilent SAS output is unregulated.

Note: See chapter 8 for more information about these registers.

STAT:QUES?

This query returns the value of the Questionable Event register. The Event register is a read-only register which holds (latches) all events that are passed by the Questionable NTR and/or PTR filter. Reading the Questionable Event register clears it.

Query Syntax
STAT:QUEStionable[:EVENt]? (None)

Returned Parameters
<NR1> (Register Value)

Examples
STAT:QUES? STATUS:QUESTIONABLE:EVENT?

Related Commands
*CLS STAT:QUES:ENAB STAT:QUES:NTR
STAT:QUES:PTR

STAT:QUES:COND?

This query returns the value of the Questionable Condition register. That is a read-only register which holds the real-time (unlatched) questionable status of the Agilent SAS.

Query Syntax
STAT:QUEStionable:CONDition? (None)

Returned Parameters
<NR1> (Register value)

Examples
STAT:QUES:COND? STATUS:QUESTIONABLE:CONDITION?

Related Commands

STAT:QUES:ENAB

This command and its query set and read the value of the Questionable Enable register. This register is a mask for enabling specific bits from the Questionable Event register to set the questionable summary bit (QUES) of the Status Byte register. This bit (bit 3) is the logical OR of all the Questionable Event register bits that are enabled by the Questionable Status Enable register.

Command Syntax
STAT:QUEStionable:ENABle <NRf>

Parameters
0 to 32767

Suffix
(None)

Default Value
0

Examples
STAT:QUES:ENAB 20 STAT:QUES:ENAB 16

Query Syntax
STAT:QUEStionable:ENABle?

Returned Parameters
<NR1> (Register value)

Related Commands
STAT:QUES?
STAT:QUES NTR/PTR Commands

These commands allow you to set or read the value of the Questionable NTR (Negative-Transition) and PTR (Positive-Transition) registers. These registers serve as polarity filters between the Questionable Enable and Questionable Event registers to cause the following actions:

- When a bit in the Questionable NTR register is set to 1, then a 1-to-0 transition of the corresponding bit in the Questionable Condition register causes that bit in the Questionable Event register to be set.
- When a bit of the Questionable PTR register is set to 1, then a 0-to-1 transition of the corresponding bit in the Questionable Condition register causes that bit in the Questionable Event register to be set.
- If the same bits in both NTR and PTR registers are set to 1, then any transition of that bit at the Questionable Condition register sets the corresponding bit in the Questionable Event register.
- If the same bits in both NTR and PTR registers are set to 0, then no transition of that bit at the Questionable Condition register can set the corresponding bit in the Questionable Event register.

Note: Setting a bit in the value of the PTR or NTR filter can of itself generate positive or negative events in the corresponding Questionable Event register.

System Commands

System commands read back system errors and the SCPI version number.

**SYST:ERR?**

This query returns the next error number followed by its corresponding error message string from the remote programming error queue. The queue is a FIFO (first-in, first-out) buffer that stores errors as they occur. As it is read, each error is removed from the queue. When all errors have been read, the query returns 0, **NO ERROR**. If more errors are accumulated than the queue can hold, the last error in the queue will be *350, TOO MANY ERRORS* (see appendix C for error codes).

You can use the Agilent SAS front panel Error key to read errors from the queue. Errors generated at the front panel are not put into the queue but appear immediately on the display.

**Trigger Subsystem**

The commands in this subsystem only apply in Fixed mode. This subsystem controls the output triggering of the Agilent SAS. Trigger commands control the remote triggering of the Agilent SAS. Initiate commands initialize the trigger system.

**ABOR**

This command cancels any trigger actions presently in process. Pending trigger levels are reset equal to their corresponding immediate values. ABOR also resets the WTG bit in the Operation Condition Status register (see chapter 4). If INIT:CONT ON has been programmed, the trigger subsystem initiates itself immediately after ABOR, thereby setting WTG. ABOR is executed at power turn on and upon execution of *RCL or RST.

<table>
<thead>
<tr>
<th>Command Syntax</th>

</table>
When the trigger subsystem is enabled, TRIG generates a trigger signal. The trigger will then:

1. Initiate a pending level change as specified by CURR[:LEV]:TRIG or VOLT[:LEV]:TRIG.
2. Clear the WTG bit in the Status Operation Condition register.
3. If INIT:CONT has been given, the trigger subsystem is immediately re-enabled for subsequent triggers. As soon as it is cleared, the WTG bit is again set to 1.

**Command Syntax**

```
TRIGger[:IMMediate]
```

**Parameters**

(None)

**Examples**

```
TRIG     TRIGGER:IMMEDIATE
```

**Related Commands**

ABOR CURR:TRIG INIT *TRG VOLT:TRIG

**TRIG:SOUR**

This command selects the trigger source. Since the Agilent SAS has no other trigger source than the GPIB bus, this command need not be used. It is included in the command set to provide programming compatibility with other instruments (such as the Agilent Electronic Load family) that may have more than one trigger source.

**Command Syntax**

Status Reporting

Agilent SAS Status Structure

Figure 8-1 shows the status register structure of the Agilent SAS. The Standard Event, Status Byte, and Service Request Enable registers and the Output Queue perform standard GPIB functions as defined in the IEEE 488.2 Standard Digital Interface for Programmable Instrumentation. The Operation Status and Questionable Status registers implement status functions specific to the Agilent SAS. Table 8-2 and Figure 8-1 show the bit configuration of each status register.

Operation Status Group

Register Functions

The Operation Status registers record signals that occur during normal operation. The group consists of the following registers:

- A Condition register that holds real-time status of the circuits being monitored. It is a read-only register.
- A PTR/NTR (positive transition/negative transition) Filter that functions as described under STAT:OPER:NTR|PTR COMMANDS in chapter 7 - Language Dictionary. This is a read/write register.
- An Event register that latches any condition that is passed through the PTR or NTR filters. Reading the Event register clears it.
- An Enable register that functions as described under STAT:OPER:ENAB in chapter 7 - Language Dictionary. This is a read/write register.

The outputs of the Operation Status group are logically-ORed into the OPER(ation) summary bit (7) of the Status Byte register.

Register Commands

Commands that access this group are derived from the STAT:OPER commands described in chapter 7 - Language Dictionary and summarized in Table 8-1.

Figure 8-1. Agilent SAS Status Model
Questionable Status Group

Register Functions
The Questionable Status registers record signals that indicate abnormal operation of the Agilent SAS. As shown in Figure 8-1, the group consists of the same type of registers as the Status Operation group. The outputs of the Questionable Status group are logically-ORed into the QUES(tionable) summary bit (3) of the Status Byte register.

Register Commands
Programming for this group is derived from the STAT:QUES commands described in chapter 7 - Language Dictionary and summarized in Table 8-3.

Standard Event Status Group

Register Functions
This group consists of an Event register and an Enable register that are programmed by common commands. The Standard Event Status Event register latches events relating to interface communication status (see Figure 8-1). It is a read-only register that is cleared when read.

Read query \*ESR?

Cleared by \*CLS \*ESR?

The Standard Event Status Enable register functions similarly to the enable registers of the Operation and Questionable status groups. The outputs of the Standard Event Status Group are logically-ORed into the RSB summary bit (5) of the Status Byte register.

Register Commands
The common \*ESE command programs specific bits in the Standard Event Status Enable register. Because the Agilent SAS implements \*PSC, the register is cleared at power on if \*PSC = 1. \*ESR? reads the Standard Event Status Event register and reading the register clears it.

Programmed by \*ESE <NRf>

Read query \*ESE?

Cleared by \*ESE 0

STATUS BYTE REGISTER

This register summarizes the information from all other status groups as defined in the "IEEE 488.2 Standard Digital Interface for Programmable Instrumentation" standard. The bit configuration is shown in Figure 8-1 and Table 8-2. The register can be read either by a serial poll or by \*STB?. Both methods return the same data, except for bit 6. Sending \*STB? returns MSS in bit 6, while polling the register returns RQS in bit 6.
The RQS Bit
Whenever the Agilent SAS requests service, it sets the SRQ interrupt line true and latches RQS into bit 6 of the Status Byte register. When the controller services the interrupt, RQS is cleared inside the register and returned in bit position 6 of the response. The remaining bits of the Status Byte register are not disturbed.

The MSS Bit
This is a real-time (unlatched) summary of all Status Byte register bits that are enabled by the Service Request Enable register. MSS is set whenever the Agilent SAS has at least one reason (and possibly more) for requesting service. Sending *STB? reads the MSS in bit position 6 of the response. No bits of the Status Byte register are cleared by reading it.

Determining the Cause of a Service Interrupt
You can determine the reason for an SRQ by the following actions:

- Use a serial poll or the *STB? query to determine which summary bits are active.
- Read the corresponding Event register for each summary bit to determine which events caused the summary bit to be set. When an Event register is read, it is cleared. This also clears the corresponding summary bit.
- The interrupt will recur until the specific condition that caused each event is removed. If this is not possible, the event may be disabled by programming the corresponding bit of the status group Enable register or NTR|PTR filter. A faster way to prevent the interrupt is to disable the service request by programming the appropriate bit of the Service Request Enable register.

Service Request Enable Register
This register is a mask that determines which bits from the Status Byte register will be ORed to generate a service request (SRQ). The register is programmed with the *SRE common command. When the register is cleared, no service requests can be generated to the controller.

Output Queue
The Output Queue is a first-in, first-out (FIFO) data register that stores Agilent SAS-to-controller messages until the controller reads them. Whenever the queue holds one or more bytes, it sets the MAV bit (4) of the Status Byte register. If too many unread error messages are accumulated in the queue, a system error message is generated (see appendix D). The Output Queue is cleared at power on and by *CLS.

Initial Conditions At Power On
Status Registers
When the Agilent SAS is turned on, a sequence of commands initializes the status registers. For the factory-default *RST power-on state, Table 8-4 shows the register states and corresponding power-on commands.

<table>
<thead>
<tr>
<th>Register</th>

</tr>
</tbody>
</table>

\(^1\)If PSC=1. If PSC = 0, the last previous state before turn on is recalled. The value of PSC is stored in nonvolatile memory.
The PON (Power-On) Bit
The PON bit in the Standard Event register is set whenever the Agilent SAS is turned on. The most common use for PON is to generate an SRQ at power on following an unexpected loss of power. To do this, bit 7 of the Standard Event Enable register must be set so that a power-on event registers in the ESB (Standard Event Summary Bit). Also, bit 5 of the Service Request Enable register must be set to permit an SRQ to be generated. The commands to accomplish these two conditions are:

*ESE 128
*SRE 32

If *PSC is programmed to 0, the contents of the Standard Event Enable and Service Request Enable registers are saved in nonvolatile memory and recalled at power on. This allows a PON event to generate SRQ at power on. Programming *PSC to 1 prevents these registers from being saved and they are cleared at power on. This prevents a PON event from generating SRQ at power on.

Examples

Note
These examples are generic SCPI commands. See chapter 6 - Remote Programming for information about encoding the commands as language strings.

Servicing an Operation Status Mode Event
This example assumes you want a service request generated whenever the Agilent SAS switches to the CC (constant current) mode. From Figure 8-1, note that the required path is for a condition at bit 10 (CC) of the Operation Status register to set bit 6 (RQS) of the Status Byte register. The required register programming is shown in Table 8-5.

Table 8-5. Generating RQS from the CC Event

<table>
<thead>
<tr>
<th>Register</th>
<th>Command</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation PTR</td>
<td>STAT:OPER:PTR 1024</td>
<td>Allows a positive transition at the CC input (bit 10) to be latched into the Operation Status Event register.¹</td>
</tr>
<tr>
<td>Operation Enable</td>
<td>STAT:OPER:ENAB 1024</td>
<td>Allows the latched CC event to be summed into the OPER summary bit.</td>
</tr>
<tr>
<td>Service Request Enable</td>
<td>*SRE 128</td>
<td>Enables the OPER summary bit from the Status Byte register to generate RQS.</td>
</tr>
<tr>
<td>Operation Condition</td>
<td>STAT:OPER:EVEN?</td>
<td>When you service the request, read the event register to determine that bit 10 (CC) is set and to clear the register for the next event.</td>
</tr>
</tbody>
</table>

¹All bits of the PTR registers bits are set to 1 at power on or in response to STAT:PRES.

Adding More Operation Events
To add the CV (constant voltage) event to this example, it is only necessary to add the decimal values for bit 8 (value 256) to the programming commands of the Operation Status group. The commands to do this are:

STAT:OPER:PTR 1280;ENAB 1280

It is not necessary to change any other registers, since the programming for the operation summary bit (OPER) path has already been done.

Servicing Questionable Status Events
To add OC (overcurrent) and OT (overtemperature) events to this example, program Questionable Status group bits 1 and 4.

STAT:QUES:PTR 18;ENAB 18

Next, you must program the Service Request Enable register to recognize both the questionable (QUES) and the operational (OPER) summary bits.

*SRE 136
Now when there is a service request, read back both the operational and the questionable event registers.

```
STAT:OPER:EVEN?;QUES:EVEN?
```

**Monitoring Both Phases of a Status Transition**

You can monitor a status signal for both its positive and negative transitions. For example, to generate RQS when the Agilent SAS either enters the CC (constant current) condition or leaves that condition, program the Operational Status PTR/NTR filter as follows:

```
STAT:OPER:PTR 1024;NTR 1024
STAT:OPER:ENAB 1024;*SRE 128
```

The PTR filter will cause the OPER summary bit to set RQS when CC occurs. When the controller subsequently reads the event register (STAT: OPER: EVEN?), the register is cleared. When CC subsequently goes false, the NTR filter causes the OPER summary bit to again set RQS.

---

**SCPI Command Completion**

SCPI commands sent to the Agilent SAS are processed either sequentially or in parallel. Sequential commands finish execution before a subsequent command begins. Parallel commands allow other commands to begin executing while the parallel command is still executing. Commands that affect trigger actions are among the parallel commands.

The *WAI, *OPC, and *OPC? common commands provide different ways of indicating when all transmitted commands, including any parallel ones, have completed their operations. The syntax and parameters for these commands are described in chapter 7. Some practical considerations for using these commands are as follows:

- **WAI**
  This prevents the Agilent SAS from processing subsequent commands until all pending operations are completed.

- **OPC?**
  This places a 1 in the Output Queue when all pending operations have completed. Because it requires your program to read the returned value before executing the next program statement, *OPC? can be used to cause the controller to wait for commands to complete before proceeding with its program.

- **OPC**
  This sets the OPC status bit when all pending operations have completed. Since your program can read this status bit on an interrupt basis, *OPC allows subsequent commands to be executed.

**Note**

The trigger subsystem must be in the Idle state in order for the status OPC bit to be true. Therefore, as far as triggers are concerned, OPC is false whenever the trigger subsystem is in the Initiated state.

---

**DFI (Discrete Fault Indicator)**

Whenever a fault is detected in the Agilent SAS, it is capable of generating a FLT signal at the digital port (see appendix C - Digital Port Functions). The source for the DFI signal can be any Questionable, Operation, or Standard Event status event (see Figure 8-1).
RI (Remote Inhibit)

Whenever a remote inhibit signal is received at the digital port (see appendix C - Digital Port Functions), the Agilent SAS will receive an RI event at the Questionable Status register. By programming the status subsystem, you may use RI to generate a service request (SRQ) to the controller and/or to create a DFI output at the digital port. By using RI/DFI in this way, you can chain the power supplies to create a serial shutdown in response to the INH input.

To enable the OV, OC, OT, and the RI conditions to generate an FLT signal, program the Questionable Status register as follows:

```
STAT:QUES:ENAB 531
```

Using Device Clear

You can send a device clear at any time to abort a SCPI command that may be hanging up the GPIB interface. The status registers, the error queue, and all configuration states are left unchanged when a device clear message is received. Device clear performs the following actions:

- The input and output buffers of the dc source are cleared.
- The dc source is prepared to accept a new command string.

The following statement shows how to send a device clear over the GPIB interface using Agilent BASIC:

```
CLEAR 705
```

IEEE-488 Device Clear

The following statement shows how to send a device clear over the GPIB interface using the GPIB command library for C or QuickBASIC:

```
IOCLEAR (705)
```
Specifications and Application Information

Specifications and Supplemental Characteristics

Performance specifications are warranted over a temperature range of 0 to 40°C unless specified otherwise. Unless otherwise noted, specifications apply to Fixed, Simulator, and Table modes. Supplemental Characteristics are not warranted but are descriptions of performance determined either by design or type testing.

1 There is no maximum impedance restriction. Therefore, Imp can be less than or equal to Isc.
2 In Simulator mode, the output current is related to the readback output voltage by an internal algorithm. In Table mode, the output current is related to the readback output voltage by interpolation between points that are entered by the user.
3 The unit may go out of specification when subjected to RF fields of 3 volts/meter in the frequency range of 26 MHz to 1 GHz.

Agilent E4351B
Constant Current Operation
Voltage: 80 V
Current: 3.95 A
Peak Power Tracker Application

The peak power tracker is a customer-provided application. In this application, the load is constantly searching for the maximum power point of the I-V curve. To achieve this the peak power tracker sweeps around the peak power point. The Agilent SAS can be used in this application in either Simulator mode or in Table mode. Note that the ability of the Agilent SAS to track the I-V curve depends on both the excursion from the peak power point and the modulation frequency.

The following graph depicts the Agilent SAS peak power tracking error for both models. The load is sinusoidally swept from -5%, -10%, or -15% on one side of Pmp to -5%, -10% or -15% on the other side of Pmp. As the frequency of the sweep is increased, the tracking error will increase as indicated by the graph.
### Exponential Model Equations*

The following equations describe the solar array simulator exponential model using the parameters $R_s$, $N$, and $a$, which are defined as functions of the four input parameters.

\[
R_s = \frac{V_{oc} - V_{mp}}{I_{mp}}
\]

\[
N = \frac{\ln(2 - 2^\alpha)}{\ln\left(\frac{I_{mp}}{I_{sc}}\right)}
\]

\[
a = -\frac{V_{mp}}{V_{oc}}\left(1 + \frac{R_s I_{sc}}{V_{oc}}\right) + R_s (I_{mp} - I_{sc})
\]

\[
V = \frac{V_{oc} \ln\left(\frac{I_{mp}}{I_{sc}}\right)^N}{\ln(2) + \frac{R_s I_{sc}}{V_{oc}}}
\]

Note that these equations tend to be most accurate for curves that are somewhat rectangular.** Figure A-2 indicates the potential range of $P_{mp}$ error percent due to the modeling equation. The x-axis parameter is $(V_{oc}/V_{mp}) \times (I_{sc}/I_{mp})$, which is a measure of the rectangularity of the simulator curve, with values near 1 being highly rectangular. The y-axis is a measure of the possible error of the curve algorithm equation at the peak power point as defined by the following equation:

\[
\% P_{mp_{error}} = \left(\frac{\text{Equation}_{P_{mp}}}{I_{mp}/V_{mp}} - 1\right) \times 100\%
\]

For example, a curve with the reference settings described in figure A-1 gives an x-axis value of 1.16, with an equation accuracy for $P_{mp}$ that is better than 1%.

---

**The potential error between the equation’s actual peak power and the expected peak power ($V_{mp} \times I_{mp}$) will increase as the curves become less rectangular.
**Series Switching Regulation**

In this application, regulation across the load can be achieved by controlling the duty cycle of a series FET, which can be operated at frequencies as high as 50kHz. A proprietary non-dissipative clamp circuit minimizes output voltage overshoots when the output of the Agilent SAS is quickly unloaded.

### Reference Settings

**Agilent E4350B**
- $V_{oc}$: 65V
- $V_{mp}$: 60V
- $I_{mp}$: 7.5A
- $I_{sc}$: 8A
- $P_{mp}$: 450W

### Circuit Diagram

![Circuit Diagram](image)

**Agilent E4350B Waveforms**

![Waveforms](image)

### Shunt Switching Regulation

In this application, regulation across the load is achieved by controlling the duty cycle of a shunt FET, which can be operated at frequencies as high as 50kHz. Note the relatively clean output current waveform, which can be attributed to the fast dynamic response and low output capacitance of the Agilent SAS.

### Reference Settings

**Agilent E4351B**
- $V_{oc}$: 130V
- $V_{mp}$: 120V
- $I_{mp}$: 3.75A
- $I_{sc}$: 4A
- $P_{mp}$: 450W

Verification and Calibration

Introduction

This appendix includes verification and calibration procedures for the Agilent E4350B and E4351B SAS. Instructions are given for performing the procedures either from the front panel or from a controller over the GPIB.

The verification procedures do not check all the operating parameters, but verify that the Agilent SAS is performing properly. Performance Tests, which check all the specifications of the dc source, are given in the applicable Service Manual. The required test equipment and acceptable test results are specified in tables in this appendix.

Note

Performance Tests, which check all the specifications of the Agilent SAS, are given in the Service Manual.

Test Equipment Required

The following equipment is required to perform the tests:

<table>
<thead>
<tr>
<th>Equipment</th>
<th>Characteristics</th>
<th>Recommended Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digital Voltmeter</td>
<td>Resolution: 10 nV @ 1 V</td>

</tr>
<tr>
<td>For Calibration Over the GPIB</td>
<td>HP Vectra (or IBM compatible) with GPIB Interface, or Agilent BASIC series</td>
<td></td>
</tr>
</tbody>
</table>

Current Monitoring Resistor

The 4-terminal current-monitoring resistor listed in Table B-1 is required to eliminate output current measurement error caused by voltage drops in leads and connections. The specified resistors have special current-monitoring terminals inside the load connection terminals. Connect the DVM directly to these current-monitoring terminals.

![Figure B-1. Verification and Calibration Test Setup](image)
Verification

General Measurement Techniques

Figure B-1 shows the setup for the tests. Be certain to use load leads of sufficient wire gauge to carry the output current (see Table 4-1). To avoid noise pickup, use coaxial cable or shielded pairs for the test leads.

Programming the Agilent SAS

Table 7-3 in chapter 7 list the programming voltage and current ranges for each model. Enter the appropriate values from the front panel. The programming procedures assume you know how to operate the Agilent SAS from the front panel (see chapter 5 - Front Panel Operation).

Order of Tests

Perform the following tests for operation verification. Test 1 must be done first, followed by Tests 2 and 3 in any order.

1. Turn-on Checkout
2. Voltage Programming and Readback Accuracy
3. Current Programming and Readback Accuracy

Turn-on Checkout

Perform the Turn-on Checkout as directed in chapter 3 - Turn-on Checkout.

Note: The Agilent SAS must pass turn-on selftest before you can proceed with these tests.

Voltage Programming and Readback Accuracy

This test verifies that the voltage programming, GPIB readback, and front panel display functions are within specifications. Figure B-1 shows the setup for the tests. Measure the dc output voltage directly at the sense connections of the output terminals or bus bars. Connect the output as shown.

<table>
<thead>
<tr>
<th>Action</th>
<th>Normal Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Turn off the Agilent SAS and connect a DVM across the sense terminals (see Figure B-1(1)).</td>
<td>CV annunciator on. Output current near 0.</td>
</tr>
<tr>
<td>2. Turn on the Agilent SAS with no load and program the output for 0 volts and maximum programmable current.</td>
<td>Readings within Low Voltage limits (see Table B-4 for either Agilent E4350B or Agilent E4351B).</td>
</tr>
<tr>
<td>3. Record voltage readings of voltmeter ($V_{DVM}$) and front panel display readback ($V_{FP}$) in Table B-4.</td>
<td></td>
</tr>
<tr>
<td>4. Program voltage to full scale (either 60 V or 120 V).</td>
<td>Readings within High voltage limits (see Table B-4 for either Agilent E4350B or Agilent E4351B).</td>
</tr>
<tr>
<td>5. Record voltage readings of voltmeter ($V_{DVM}$) and front panel display readback ($V_{FP}$) in Table B-4.</td>
<td></td>
</tr>
</tbody>
</table>
Current Programming and Readback Accuracy

This test verifies that the current programming and readback are within specification. Connect the appropriate current monitoring resistor (see Table B-1) as shown in Figure B-1(2). The accuracy of the resistor must be as specified in the table.

Table B-3. Current Programming and Readback Accuracy Test

<table>

* Enter your test results in this column.

**Calibration**

**Important** The Agilent SAS can only be calibrated in Fixed mode. Mode switching is accomplished over the GPIB bus via the SCPI CURRent:MODE command.

The Agilent SAS may be calibrated either from the front panel or from a controller over the GPIB. The procedures given here apply to both models. The recommended calibration interval is once a year. Note that these instructions do not include verification procedures. If you need to perform verification as a prerequisite to or as part of your calibration procedure, see “Verification”.

**Test Equipment Required**

The equipment listed in Table B-1, or equivalent, is required for calibration.

**General Procedure**

**WARNING** Because the Agilent SAS output must be enabled during calibration, voltages or currents hazardous to personnel and/or damaging to equipment can appear at the output terminals.

**Parameters Calibrated**

The following parameters may be calibrated:

- Output voltage.
- Output voltage readback.
- Overvoltage protection (OVP).
- Output current.
- Output current readback.

You do not have to do a complete calibration each time. If appropriate, you may calibrate only the voltage or current and proceed to "Saving the Calibration Constants".

Figure B-1 shows the test setups required for voltage and current calibration.
Front Panel Calibration

Eight shifted keys and the Entry keypad are used for calibration functions (see chapter 5 - Front Panel Operation for explanations of shifted keys and the Entry keypad). The following procedures assume you understand how to operate front panel keys.

Entering the Calibration Values

Follow the steps in Table B-5 for entering calibration values.

Saving the Calibration Constants

CAUTION Storing calibration constants overwrites the existing ones in nonvolatile memory. If you are not absolutely sure you want to permanently store the new constants, omit this step. The Agilent SAS calibration will then remain unchanged.

To replace any existing calibration constants with ones you have just entered, press Cal Save. CAL SAVED then appears on the display.

Disabling the Calibration Mode

To disable the calibration mode, press Cal Disable. The display will return to meter mode with the Cal annunciator off.

Changing the Calibration Password

The factory default password is the model number of your supply, such as 4350. You can change the calibration password only when the Agilent SAS is in the calibration mode (which requires you to enter the existing password). Proceed as follows:

2. Enter the new password from the keypad. (You can use up to 6 integers and an optional decimal point.) If you want Cal Disable to operate without requiring any password, change the password to 0 (zero).
3. AGAIN will appear on the display. Enter the password a second time.
4. When OK is displayed, the new password has been accepted.

#### Entering Current Calibration Values

1. Make certain appropriate shunt resistor (see Table A-1) is the only load on the Agilent SAS.  
2. Select the first calibration point by pressing \( \text{Ical} \).  
   If the Agilent SAS is not in CC mode, an error occurs.  
3. Wait for DVM reading to stabilize. Then read DVM and compute the first current value  
(DVM reading ÷ shunt resistance).  
4. Use Entry keypad to enter the first current value.  
5. Select second calibration point by pressing \( \text{Ical} \) again.  
6. Wait for DVM reading to stabilize. Then read DVM and compute the second  
current value (DVM reading ÷ shunt resistance).  
7. Use Entry keypad to enter the second current value.  
   **Note:** If the entered value is not within acceptable range, an error occurs.  
   *Wait for the Agilent SAS to compute the new current calibration constants, which will be  
   stored in RAM.* | \( \text{(Meter mode)} \)  
IRDG1  
WRONG MODE  
(Meter mode)  
IRDG2  
(Meter mode)  
CAL ERROR  
CAL COMPLETE |

### NOTES

1. If **CAL DENIED** appears, then an internal jumper has been set to prevent the calibration from being changed. (See the  
   *Service Manual.*)  
2. If the active password is lost, the calibration function can be recovered by moving an internal jumper that defeats  
   password protection. However, this also will change all calibration constants to their factory-default values. (For more  
   information, see the *Service Manual.*)  
3. Program the output current to 10% of its rated output*  
4. Program the output voltage to 10% of its rated output*  

* See applicable Output Ratings in appendix A
Recovering From Calibration Problems

You can encounter serious calibration problems if you cannot determine a calibration password that has been changed or the Agilent SAS is severely out of calibration. There are jumpers inside the Agilent SAS that permit the calibration password to be defeated and allow the original factory calibration constants to be restored. These jumpers are explained in the Service Manual.

Calibration Error Messages

Error messages that can occur during calibration are shown in Table B-6.

<table>
<thead>
<tr>

Calibration Over The GPIB

You can calibrate the Agilent SAS by using SCPI commands within your controller programming statements. Be sure you are familiar with calibration from the front panel before you calibrate from a controller. The SCPI calibration commands are related to the front panel calibration controls as follows:

<table>
<thead>
<tr>

<td></td>
<td>CAL:SAVE</td>
</tr>
</tbody>
</table>

Calibration Example

A sample calibration program is given at the end of this appendix. If your system is Agilent BASIC, you can use the program with very little modification. Otherwise, use it as a guide for writing your own program.
Calibration Language Dictionary

The calibration commands are listed in alphabetical order. The format for each command follows that shown in chapter 7 - Language Dictionary. Calibration error messages that can occur during GPIB calibration are shown in Table B-6.

CAL:CURR

This command is used to calibrate the output current. The command enters current value that you obtain from an external meter. (If you are entering the current value, allow time for the DVM to stabilize.) You must first select a calibration level (CAL:CURR:LEV) for the value being entered. Two successive values (one for each end of the calibration range) must be selected and entered. The Agilent SAS then computes new current calibration constants. These constants are not stored in nonvolatile memory until saved with the CAL:SAVE command.

Command Syntax CALibrate:CURRent[:DATA] <NRf>

Parameters (See applicable Output Ratings specification in appendix A)

Default Suffix A

Examples CAL: CURR 32 . 33 A  CAL: CURR: DATA 5 . 00

Related Commands CAL:SAVE CAL:STAT

CAL:CURR:LEV

This command sets the Agilent SAS to a calibration point that is then entered with CAL:CURR[:DATA]. During calibration, two points must be entered and the low-end point (MIN) must be selected and entered first.

Command Syntax CALibrate:CURRent:LEVel {MIN|MAX}

Parameters {<CRD>|MINimum|MAXimum}

Examples CAL: CURR: LEV MIN  CAL: CURR: LEV MAX

Related Commands CAL:CURR[:DATA]  CAL:STAT

CAL:PASS

This command enters a new calibration password. The command is active only when the Agilent SAS is already in the calibration mode. Unless it is changed subsequently to shipment, the password is the Agilent SAS's model number. If the password is set to 0, password protection is removed and CAL:STAT ON is unrestricted. A new password is automatically stored in nonvolatile memory and does not have to be stored with the CAL:SAVE command.

Command Syntax CALibrate:PASScode <NRf>

Parameters <NRf>

Examples CAL:PASS 4350          CAL:PASS   09.1993

Related Commands CAL:STAT

CAL:SAVE

This command saves any new calibration constants (after a current or voltage calibration procedure has been completed) in nonvolatile memory.

Command Syntax: CALibrate:SAVE

Parameters (None)

Examples CAL: SAVE

Related Commands CAL:CURR  CAL:VOLT  CAL:STAT
CAL:STAT

This command enables and disables the calibration mode. The calibration mode must be enabled before the Agilent SAS will accept any other calibration commands. The first parameter specifies the enabled or disabled state. The second parameter is the password. It is required if the calibration mode is being enabled and the existing password is not 0. If the second parameter is not entered or is incorrect, an error is generated and the calibration mode remains disabled. The query statement returns only the state, not the password. Note that whenever the calibration mode is changed from enabled to disabled, any new calibration constants are lost unless they have been stored with CAL:SAVE.

**Command Syntax:**

```
CALibrate:STATe <bool> [,<NRf>]
```

**Parameters**

{0 | OFF} | {1 | ON} [,<NRf>]

**RST Value**

OFF

**Examples**

CAL:STAT 1,4350     CAL:STAT OFF

**Query Syntax**

```
CALibrate:STATe?
```

**Returned Parameters**

{0 | 1 }

**Related Commands**

CAL:PASS    CAL:SAVE

CAL:VOLT

This command is used to calibrate the output voltage. The command enters voltage value that you obtain from an external meter. (If you are entering the voltage value, allow time for the DVM to stabilize.) You must first select a calibration level (CAL:VOLT:LEV) for the value being entered. Two successive values (one for each end of the calibration range) must be selected and entered. The Agilent SAS then computes new voltage calibration constants. These constants are not stored in nonvolatile memory until saved with the CAL:SAVE command.

**Command Syntax**

```
CALibrate:VOLTage[:DATA] <NRf>
```

**Parameters**

(See applicable Output Ratings in appendix A)

**Default Suffix**

A

**Examples**

CAL: VOLT 322 . 5 MV  CAL: VOLT: DATA 3 . 225

**Related Commands**

CAL:SAVE   CAL:STAT

CAL:VOLT:LEV

This command sets the Agilent SAS to a calibration point that is then entered with CAL:VOLT[:DATA]. During calibration, two points must be entered and the low-end point (MIN) must be selected and entered first.

**Command Syntax**

```
CALibrate:VOLTage:DATA {MIN|MAX}
```

**Parameters**

{ < CRD > | MINimum | MAXimum}

**Examples**

CAL: VOLT: LEV MIN           CAL: VOLT: LEV MAX

**Related Commands**

CAL:VOLT[:DATA]        CAL:STAT

CAL:VOLT:PROT

This command calibrates the Agilent SAS overvoltage protection (OV) circuit. The output voltage must be in calibration before this procedure is performed. Also, the Agilent SAS output must be enabled and operating in the constant voltage (CV) mode. If present, the optional relay accessory must either be disconnected or set to the off (open) state. The Agilent SAS automatically performs the calibration and stores the new OV constant in nonvolatile memory. CAL:VOLT:PROT is a sequential command that takes several seconds to complete.

**Command Syntax**

```
CALibrate:VOLTage:PROTection
```

**Parameters**

(None)

**Example**

CAL: VOLT: PROT

**Related Commands**

CAL:STAT
The following program can be run on any controller operating under Agilent BASIC. The assumed Agilent SAS address is 5 and calibration password is 4350. If required, change these parameters in the appropriate statements.

Digital Port Functions

Digital Connector

A 4-pin connector and a quick-disconnect mating plug are provided for digital input and output signals (see Figure C-1 for wiring connections and appendix A for electrical characteristics). This digital port can be configured to provide either Fault/Inhibit or Digital I/O functions.

Note

Consistent with good engineering practice, twist and shield all signal wires to and from the digital connector.

![Figure C-1. Digital Port Connector](image)

Fault/Inhibit Operation

As shipped from the factory, the digital port is configured to provide a fault indicator (FLT) output and a remote (INH) input. Unplug the mating plug to make the connections. After you have finished making all connections, plug the wired plug back into the connector.

**FLT Output**

(pins 1 and 2)

Used to indicate that a fault has occurred in power supply. Pins 1 and 2 are the open collector output of an optocoupler, with pin 1 the collector and pin 2 the emitter. When a fault has occurred, pin 1 is driven low with respect to pin 2 (negative-true).

**INH Input**

(pin 3)

Used to shut down the power supply output. Pin 3 is a high impedance input. The supply shuts down when this input is driven low (negative-true). This can be done by shorting pin 3 to pin 4.

**INH Common**

(pin 4)

Provides the common connection for the INH input.

Three examples are provided to show how to use the FLT/INH circuits of your power supply. Use twisted wire connections to reduce or prevent EM in all cases. If shielded wire is used, connect only one end of the shield to the chassis signal ground binding post to prevent ground loops.

In Figure C-2, the INH input is connected to a switch that shorts pin 3 to pin 4 whenever it is necessary to externally disable the output of the supply. This will activate the remote inhibit (RI) fault protection circuit, causing the front panel Prot annunciator to come on. It also sets the RI event bit in the supply’s Questionable Status Event register (see chapter 8 - Status Reporting). To re-enable the supply after it has been disabled by the INH input, first open the connection between pins 3 and 4. Then clear the protection circuit either from the front panel (see chapter 5) or over the GPIB (see chapter 8).
In Figure C-3A, the FLT output is connected to a relay driver circuit that energizes a relay whenever a fault condition occurs in the power supply. The relay can be used to physically disconnect the output of the power supply from the load. The FLT output is generated by the logical ORing of the power supply’s Operation, Questionable, and Event status summary bits (see chapter 8). You can cause one or more events to activate the FLT output by enabling the appropriate events in these status registers. The fault condition is cleared by first removing the cause of the fault and then reading the appropriate status event register(s).

In Figure C-3B, the FLT output of one supply is connected to the INH input of another supply. Although only two supplies are shown, it is possible to chain other supplies with this arrangement. A fault condition in any one of the power supplies will disable all of them without intervention either by the controller or external circuitry. The controller can be made aware of the fault via a service request (SRQ) generated by the Questionable Status summary bit (see chapter 8).
Changing The Port Configuration

As shipped from the factory, the digital port is configured for FLT/INH operation. You can change the configuration of the port to operate as a general-purpose digital input/output port to control your custom circuitry as shown in Figure C-4. To change the port configuration, you must move a jumper on the GPIB board.

**WARNING** Hazardous voltage can remain inside the power supply even after it has been turned off. This procedure should only be done by qualified electronics service personnel.

Proceed as follows:
1. Turn off the power supply and disconnect the power cord from the power source.
2. Remove the four screws that secure the two carrying straps and outer cover.
3. Spread the bottom rear of the cover and pull it back to disengage it from the front panel.
4. Slide the outer cover back to expose the top of the GPIB board.
5. Refer to Figure C-4 and use needle-nose pliers to move the jumper to the Digital I/O position.
6. Replace the outer cover, and secure the carrying straps.
7. Make the necessary wire connections to the digital connector.

Digital I/O Operation

The digital port can be configured (see Figure C-4) to provide a digital input/output to be used with custom digital interface circuits or relay circuits. Some examples are shown Figure C-5. See Figure C-1 for the pin assignments of the mating plug and appendix A for the electrical characteristics of the port. See DIG:DATA:[VAL] in chapter 7 - Language Dictionary for information on programming the port. The digital port pins are as follows:
OUT 0 (pin 1)  This port can only be used as an open-collector output. It is assigned a bit weight of 1.

OUT 1 (pin 2)  This port can only be used as an open-collector output. It is assigned a bit weight of 2.

IN/OUT 2 (pin 3)  This port can be programmed to be either a high impedance input or an open-collector output.

Common (pin 4)  This pin is the common connection for the Digital I/O ports.

Figure C-5. Digital I/O Port Applications
## Error Messages

### Hardware Error Messages

Front panel error messages resulting from selftest errors or runtime failures are described in chapter 3 - Turn-On Checkout.

### Calibration Error Messages

Front panel error messages resulting from calibration errors are described in appendix B.

### System Error Messages

System error messages are obtained remotely with the `SYST:ERR?` query or by pressing the front panel key. The error number is the value placed in the error queue. `SYST:ERR?` returns the error number into a variable and combines the number and the error message into a string. Table D-1 lists the system errors that are associated with SCPI syntax errors and with interface problems. Information inside the brackets is not part of the standard error message, but is included for clarification. When system errors occur, the Standard Event Status register (see chapter 8) records them as follows:

<table>
<thead>
<tr>
<th>Bit Set</th>
<th>Error Code</th>
<th>Error Type</th>
<th>Bit Set</th>

Agilent Sales and Support Offices

For more information, call your local Agilent sales office listed in your telephone directory or an Agilent regional office listed below for location of your nearest sales/support office.

United States of America:
Agilent Technologies Company
Test and Measurement Organization
5301 Stevens Creek Blvd
Bldg 51L-5C
Santa Clara, CA 95052-8059
(800) 452 4844

Europe:
Agilent Technologies
European Marketing Center
P.O. Box 999
1180 AZ Amstelveen
The Netherlands

Asia Pacific:
Agilent Technologies Asia Pacific Ltd.
17-21/F Shell Tower, Time Square
1 Matheson Street, Causeway Bay,
Hong Kong
(852) 2599 7070

Japan:
Yokogawa Agilent Technologies Ltd.
Measurement Assistance Center
9-1, Takakura-Cho, Hachioji-Shi,
Tokyo, 192, Japan
(81) 426 48 3860

Australia/New Zealand:
Agilent Technologies Australia Ltd.
31-41 Joseph Street
Blackburn, Victoria 3130
Australia
131 347 ext. 2902

Latin America:
Agilent Technologies
Latin American Region Headquarters
5200 Blue Lagoon Drive
9th Floor
Miami, Florida 33126
U.S.A.
(305) 267 4245/4220

Canada:
Agilent Technologies Canada Ltd.
5150 Spectrum Way
Mississauga, Ontario L4W 5Gl
(905) 206 4725
Manual Updates

The following updates have been made to this manual since the print revision indicated on the title page.

3/01/00

All references to HP have been changed to Agilent.
All references to HP-IB have been changed to GPIB.

Information about installing VXIplug&play instrument drivers has been added to page 21.
