Power Meter Remote Operation
**Introduction**

This chapter describes the parameters which configure the power meter and help you determine settings to optimize performance. It contains the following sections:

"Configuring the Remote Interface", on page 1-3.

"Zeroing and Calibrating the Power Meter", on page 1-8.

"Making Measurements", on page 1-11.

"Setting the Range, Resolution and Averaging", on page 1-37.

"Setting Offsets", on page 1-41.

"Setting Measurement Limits", on page 1-43.

"Measuring Pulsed Signals", on page 1-46.

"Triggering the Power Meter", on page 1-49.

"Getting the Best Speed Performance", on page 1-54.

"How Measurements are Calculated", on page 1-58.

"Status Reporting", on page 1-59.

"Saving and Recalling Power Meter Configurations", on page 1-80.

"Using Device Clear to Halt Measurements", on page 1-81.

"An Introduction to the SCPI Language", on page 1-82.

"Quick Reference", on page 1-91.

"SCPI Compliance Information", on page 1-99.
Configuring the Remote Interface

This section describes how to configure the remote interface.

HP-IB Address

Each device on the HP-IB (IEEE-488) interface must have a unique address. You can set the power meter's address to any value between 0 and 30. The address is set to 13 when the power meter is shipped from the factory.

The address is stored in non-volatile memory, and does not change when the power meter is switched off, or after a remote interface reset.

Your HP-IB bus controller has its own address. Avoid using the bus controller's address for any instrument on the interface bus. Hewlett-Packard controllers generally use address 21.

To set the HP-IB address from the front panel:

1. Press [System Inputs], HP-IB. The current HP-IB address is displayed on the HP-IB Addr softkey.
2. To change this setting press HP-IB Addr. The power meter displays the address in a pop up window on the measurement screen. Modify this address (see below) as desired.
   - Use [ or ] to modify the digit on which the cursor is currently positioned.
   - Use [ or ] to move to other digits.
3. To confirm your choice press Enter.

To set the HP-IB address from the remote interface use the:

To query the HP-IB address from the remote interface use the:

Programming Language Selection (HP EPM-441A only)

You can select one of two languages to program the power meter from the remote interface. The language is SCPI when the power meter is shipped from the factory. The other language is the HP 437B programming language.

The language selection is stored in non-volatile memory, and does not change when power has been off or after a remote interface reset.

To select the interface language from the front panel:

1. Press [System], HP-IB, Command Set.
2. Select the language you require from HP 437B and SCPI.

To select the interface language from the remote interface use the:

- `SYSTem:LANGuage` command.

To query the interface language from the remote interface use the:

- `SYSTem:LANGuage?` query.

Table 1-1 details all the HP 437B commands that the HP EPM-441A supports and their function. For a detailed description of these commands refer to the HP 437B Power Meter Operating Manual. In addition the `SYST:LANG` SCPI command allows you to return to using the SCPI programming language when in the HP 437B mode.

1. This command is accepted but has no active function.
2. This command is not an original HP 437B command. However, it can be used to set the measurement speed to 20 or 40 readings/sec in HP 437B mode. See SENSE:SPEED for more details.
3. This command is not an original HP 437B command. However, it can be used to terminate the HP 437B language and select the SCPI language. Note that it is recommended that the instrument is Preset following a language switch.
4. Always returns 0000 in HP 437B language.
Zeroing and Calibrating the Power Meter

This section describes how to zero and calibrate the power meter.

The calibration and zeroing commands are overlapped commands refer to "Using the Operation Complete Commands", on page 1-78 to determine when the commands are complete.

Zeroing

Zeroing adjusts the power meter's specified channel for a zero power reading with no power applied to the power sensor.

The command used to zero the power meter is:

CALibration[1|2]:ZERO:AUTO ONCE

The command assumes that there is no power being applied to the sensor. It turns the power reference oscillator off, then after zeroing, returns the power reference oscillator to the same state it was in prior to the command being received. Zeroing takes approximately 10 seconds depending on the type of power sensor being used.

When to Zero?

Zeroing of the power meter is recommended:

- when a 5°C change in temperature occurs.
- when you change the power sensor.
- every 24 hours.
- prior to measuring low level signals. For example, 10 dB above the lowest specified power for your power sensor.

Calibration

Calibration sets the gain of the power meter using a 50 MHz 1 mW calibrator as a traceable power reference. The power meter's POWER REF output or a suitable external reference is used as the signal source for calibration. An essential part of calibrating is setting the correct reference calibration factor for the power sensor you are using. The HP 8480 series power sensors require you to set the reference calibration factor. The HP E-series power sensors set the reference calibration factor.
automatically. Offset, relative and duty cycle settings are ignored during calibration.

The command used to calibrate the power meter is:

`CALibration[1|2]:AUTO ONCE`

The command assumes that the power sensor is connected to a 1 mW reference signal. It turns the power reference oscillator on, then after calibrating, returns the power reference oscillator to the same state it was in prior to the command being received. It is recommended that you zero the power meter before calibrating.

**Calibration Sequence**

This feature allows you to perform a complete calibration sequence with a single query. The query is:

`CALibration[1|2][:ALL]`?

The query assumes that the power sensor is connected to the power reference oscillator. It turns the power reference oscillator on, then after calibrating, returns the power reference oscillator to the same state it was in prior to the command being received. The calibration sequence consists of:

- **Zeroing the power meter** (`CALibration[1|2]:ZERO:AUTO ONCE`), and
- **calibrating the power meter** (`CALibration[1|2]:AUTO ONCE`).

The query enters a number into the output buffer when the sequence is complete. If the result is 0 the sequence was successful. If the result is 1 the sequence failed. Refer to “CALibration[1|2][:ALL]?”, on page 4-5 for further information.

**Note**

The `CALibration[1|2][:ALL]` command is identical to the `CALibration[1|2][:ALL]?` query except that no number is returned to indicate the outcome of the sequence. You can examine the Questionable Status Register or the error queue to discover if the sequence has passed or failed. Refer to “Status Reporting”, on page 1-59 for further information.
Power Meter Remote Operation
Zeroing and Calibrating the Power Meter

Setting the Reference Calibration Factor

All the HP 8480 series power sensors require you to set the reference calibration factor. The reference calibration factor can be set by:

- entering the value into the power meter using the \texttt{CALibrate[1|2]:RCFactor} command.
- selecting and enabling the sensor calibration table. The reference calibration factor is automatically set by the power meter using the reference calibration factor stored in the sensor calibration table. See “Using Sensor Calibration Tables”, on page 1-27 for further information.

Examples

a) To enter a reference calibration factor of 98.7\% for channel A, you should use the following command:
\texttt{CAL:RCF 98.7PCT}

This overrides any \texttt{RCF} previously set by selecting a sensor calibration table.

b) To automatically set the reference calibration factor, you have to use a sensor calibration table as described in “Using Sensor Calibration Tables”, on page 1-27. To select and enable the table do use the following commands:
\texttt{[SENSe[1]] | SENSe2:CORRection:CSET:SELect <string>}
\texttt{[SENSe[1]] | SENSe2:CORRection:CSET:STATe ON}

When the sensor calibration table is selected the \texttt{RCF} from the table overrides any value previously set.

Querying the Reference Calibration Factor

To determine the current reference calibration factor, use the following command:
\texttt{CALibration[1|2]:RCFactor?}
Making Measurements

The MEASure? and CONFigure commands provide the most straight-forward method to program the power meter for measurements. You can select the measurement's expected power level, resolution and with the HP EPM-442A the measurement type (that is single channel, difference or ratio measurements) all in one command. The power meter automatically presets other measurement parameters to default values as shown in Table 1-2.

Table 1-2: MEASure? and CONFigure Preset States

</tr>
</tbody>
</table>

An alternative method to program the power meter is to use the lower level commands. The advantage of using the lower level commands over the CONFigure command is that they give you more precise control of the power meter. As shown in Table 1-2 the CONFigure command presets various states in the power meter. It may be likely that you do not want to preset these states. Refer to “Using the Lower Level Commands”, on page 1-26 for further information.
Power Meter Remote Operation
Making Measurements

Using MEASURE?

The simplest way to program the power meter for measurements is by using the MEASURE? query. However, this command does not offer much flexibility. When you execute the command, the power meter selects the best settings for the requested configuration and immediately performs the measurement. You cannot change any settings (other than the expected power value, resolution and with the HP EPM-442A the measurement type) before the measurement is taken. This means you cannot fine tune the measurement, for example, you cannot change the filter length. To make more flexible and accurate measurements use the CONFIGURE command. The measurement results are sent to the output buffer. MEASURE? is a compound command which is equivalent to an ABORT, followed by a CONFIGURE, followed by a READ?.

MEASURE? Examples

The following commands show a few examples of how to use the MEASURE? query to make a measurement. It is advisable to read through these examples in order as they become increasingly more detailed. These examples configure the power meter for a measurement (as described in each individual example), automatically place the power meter in the “wait-for-trigger” state, internally trigger the power meter to take one reading, and then sends the reading to the output buffer.

These examples give an overview of the MEASURE? query. For further information on the MEASURE? commands refer to the section “MEASURE[1 2] Commands” starting on page 2-49.

Example 1 - The Simplest Method

The following commands show the simplest method of making single channel (for example A or B) measurements. Using MEAS1? will result in an upper window measurement, and MEAS2? in a lower window measurement. The channel associated with the window can be set using the source list parameter (see example 2), or will default as in this example (See “HP EPM-442A only” on page 15.).

```
  specifies window
  MEAS1?
  MEAS2?
```
Example 2 - Specifying the Source List Parameter

The MEASure command has three optional parameters, an expected power value, a resolution and a source list. These parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder.

The following example uses the source list parameter to specify the measurement channel as channel A. The expected power and resolution parameters are defaulted, leaving them at their current settings. The measurement is carried out on the upper window.

```
MEAS1? DEF,DEF,(@1)
```

The operation of the MEAS1? command when the source list parameter is defaulted is described in the note on page 1-15.

| Note | For the HP EPM-441A it is not necessary to specify a channel as only one channel is available. |

Example 3 - Specifying the Expected Power Parameter

The previous example details the three optional parameters which can be used with the MEASure? command. The first optional parameter is used to enter an expected power value. Entering this parameter is only relevant if you are using an HP E-series power sensor. The value entered determines which of the power sensor’s two ranges is used for the measurement. If the current setting of the power sensor’s range is no longer valid for the new measurement, specifying the expected power value decreases the time taken to obtain a result.

The following example uses the expected value parameter to specify a value of -50 dBm. This selects the power sensor’s lower range (refer to “Range”, on page 1-37 for details of the range breaks). The resolution parameter is defaulted, leaving it at its current setting. The source list parameter specifies a channel B measurement. The measurement is displayed on the lower window.

```
MEAS2? -50,DEF,(@2)
```
Example 4 - Specifying the Resolution Parameter

The previous examples detailed the use of the expected value and source list parameters. The resolution parameter is used to set the resolution of the specified window. This parameter does not affect the resolution of the HP-IB data, however it does affect the auto averaging setting (refer to Figure 1-2 on page 1-39).

Since the filter length used for a channel with auto-averaging enabled is dependent on the window resolution setting, a conflict arises when a given channel is set up in both windows and the resolution settings are different. In this case, the higher resolution setting is used to determine the filter length.

The following example uses the resolution parameter to specify a resolution setting of 3. This setting represents 3 significant digits if the measurement suffix is W or %, and 0.01 dB if the suffix is dB or dBm (for further details on the resolution parameter refer to the commands in Chapter 2, “MEASurement Instructions”). Also, in this example the expected power and source list parameters are defaulted. The expected power value will be left unchanged at its current setting. The source list parameter will be defaulted as described in the note on page 1-15. Note that as the source list parameter is the last specified parameter you do not have to specify DEF. The measurement is carried out on the upper window.

```
specifies window  
```

```
MEAS1? DEF, 3
```

specifies resolution setting

Example 5 - Making a Difference Measurement

The following command can only be carried out on the HP EPM-442A. It queries the lower window to make a difference measurement of channel B - channel A. The expected power and resolution parameters are defaulted, leaving them at their current settings.

```
specifies window

```

```
MEAS2:POW:AC:DIFF? DEF,DEF, (02), (01)
```

specifies between which channels the difference is calculated

Channel B - A
Example 6 - Making a Ratio Measurement

The following command can only be carried out on the HP EPM-442A. It queries the upper window to make a ratio measurement of channel A/B. The expected power and resolution parameters are defaulted, leaving them at their current settings.

![Image of command structure]

**Note**

HP EPM-442A only

The operation of the MEASure? command when the source list parameter is defaulted depends on the current setup of the window concerned (for example, A, B, A/B, A-B etc.) and on the particular command used (for example, MEAS[:POW][:AC] and MEAS[:POW][:AC]:RAT? etc).

This means that when the source list parameter is defaulted, there are a number of possibilities.

<table>

</table>
Using the CONFigure Command

When you execute this command, the power meter presets the best settings for the requested configuration (like the MEASure? query). However, the measurement is not automatically started and you can change measurement parameters before making measurements. This allows you to incrementally change the power meter’s configuration from the preset conditions. The power meter offers a variety of low-level commands in the SENSE, CALCulate, and TRIGger subsystems. For example, if you want to change the averaging use the [SENSe[1]]|SENSe2:AVERage:COUNT command.

Use the INITiate or READ? query to initiate the measurement.

Using READ?

CONFigure does not take the measurement. One method of obtaining a result is to use the READ? query. The READ? query takes the measurement using the parameters set by the CONFigure command then sends the reading to the output buffer. Using the READ? query will obtain new data.

Using INITiate and FETCH?

CONFigure does not take the measurement. One method of obtaining the result is to use the INITiate and FETCH? commands. The INITiate command causes the measurement to be taken. The FETCH? query retrieves a reading when the measurement is complete, and sends the reading to the output buffer. FETCH? can be used to display the measurement results in a number of different formats (for example, A/B and B/A) without taking fresh data for each measurement.

CONFigure Examples

The following program segments show how to use the READ? command and the INITiate and FETCH? commands with CONFigure to make measurements.

It is advisable to read through these examples in order as they become increasingly more detailed.

These examples give an overview of the CONFigure command. For further information on the CONFigure commands refer to Chapter 2, “MEASurement Instructions.”
Example 1 - The Simplest Method

The following program segments show the simplest method of querying the upper and lower window's measurement results respectively.

Using READ?

*RST  Reset instrument
CONF1 Configure upper window - defaults to a channel A measurement
READ1? Take upper window (channel A) measurement
*RST  Reset instrument
CONF2 Configure the lower window - defaults to channel A
(HP EPM-441A), Channel B (HP EPM-442A) measurement
READ2? Take lower window measurement (channel A on HP EPM-441A, B on HP EPM-442A)

Using INITiate and FETCH?

*RST  Reset instrument
CONF1 Configure upper window - defaults to a channel A measurement
INIT1 Causes channel A to make a measurement
FETCH1? Retrieves the upper window's measurement

For the HP EPM-441A only:

*RST  Reset instrument
CONF2 Configure lower window - HP EPM-441A defaults to channel A
INIT2? Causes channel A to make measurement
FETCH2? Retrieves the lower window's measurement

For the HP EPM-442A only:

*RST  Reset instrument
CONF2 Configure lower window
INIT2? Causes channel B to make measurement
FETCH2? Retrieves the lower window's measurement
Example 2 - Specifying the Source List Parameter

The CONFigure and READ? commands have three optional parameters, an expected power value, a resolution and a source list. These parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFAULT is used as a place holder.

The following examples use the source list parameter to specify the measurement channel as channel A. The expected power and resolution parameters are defaulted, leaving them at their current settings. The measurement is carried out on the upper window.

Although the READ? and FETCH? queries have three optional parameters it is not necessary to define them as shown in these examples. If they are defined they must be identical to those defined in the CONFigure command otherwise an error occurs.

| Note | For the HP EPM-441A it is not necessary to specify a channel as only one channel is available. |

Using READ?

| ABOR1 | Aborts channel A |
| CONFI  DEF,DEF,(@1) | Configures the upper window to make a channel A measurement using the current expected power and resolution settings. |
| READ1? | Takes the upper window's measurement. |

Using INITIate and FETCH?

| ABOR1 | Aborts channel A |
| CONFI  DEF,DEF,(@1) | Configures the upper window to make a channel A measurement using the current expected power and resolution settings. |
| INITI | Causes channel A to make a measurement. |
| FETCH1? | Retrieves the upper window's measurement. |
Example 3 - Specifying the Expected Power Parameter

The previous example details the three optional parameters which can be used with the CONFIGure and READ? commands. The first optional parameter is used to enter an expected power value. Entering this parameter is only relevant if you are using an HP E-series power sensor. The value entered determines which of the power sensor's two ranges is used for the measurement. If the current setting of the power sensor's range is no longer valid for the new measurement, specifying the expected power value decreases the time taken to obtain a result.

The following example uses the expected value parameter to specify a value of -50 dBm. This selects the power meter's lower range (refer to "Range", on page 1-37 for details of the range breaks). The resolution parameter is defaulted, leaving it at its current setting. The source list parameter specifies a channel B measurement. The measurement is carried out on the upper window.

Using READ?

```
ABOR2
CONF1 -50,DEF,(@2)
```

Aborts channel B
Configures the upper window to make a channel B measurement using an expected power of -50 dBm and the current resolution setting.
Takes the upper window's measurement.

```
READ1?
```

Some fine tuning of measurements can be carried out using the CONFIGure and READ? commands. For example, in the above program segment some fine tuning can be carried out by setting the filter length to 1024 and the trigger delay off.

```
ABOR2
CONF1 -50,DEF,(@2)
SENS2:AVER:COUN 1024
TRIG2:DEL:AUTO OFF
READ1?
```
Using INITiate and FETCH?

ABOR2
CONF1 -50, DEF, (@2)
INIT2
FETCH?

Aborts channel B
Configures the upper window to make a channel B measurement using an expected power of -50 dBm and the current resolution setting.
Causes channel B to make a measurement.
Retrieves the upper window's measurement.

Some fine tuning of measurements can be carried out using the CONFIGure command and INITiate and FETCH? commands. For example, in the above program segment some fine tuning can be carried out by setting the filter length to 1024 and the trigger delay off.

ABOR2
CONF1 -50, DEF, (@2)
SENS2: AVER:COUN 1024
TRIG2:DEL:AUTO OFF
INIT2
FETCH?
Example 4 - Specifying the Resolution Parameter

The previous examples detailed the use of the expected value and source list parameters. The resolution parameter is used to set the resolution of the specified window. This parameter does not affect the resolution of the HP-IB data, however it does affect the auto averaging setting (refer to Figure 1-2 on page 1-39).

Since the filter length used for a channel with auto-averaging enabled is dependent on the window resolution setting, a conflict arises when a given channel is set up in both windows and the resolution settings are different. In this case, the higher resolution setting is used to determine the filter length.

The following example uses the resolution parameter to specify a resolution setting of 3. This setting represents 3 significant digits if the measurement suffix is W or %, and 0.01 dB if the suffix is dB or dBM (for further details on the resolution parameter refer to the commands in Chapter 2, “MEASurement Instructions”). Also, in this example the expected power and source list parameters are defaulted. The expected power value will be left unchanged at its current setting. The source list parameter will be defaulted as described in the note on page 1-15. Note that as the source list parameter is the last specified parameter you do not have to specify DEF.

**Using READ?**

```
ABOR1
CONFI DEF,3
READ1?
```

Aborts channel A.  
Configures the upper window to make a measurement using the current setting of the expected power and source list and a resolution setting of 3.  
Takes the upper window's measurement. This will be a channel A or B measurement depending on current window setup.

Some fine tuning of the above program segment can be carried out for example, by setting the trigger delay off. The following program segment assumes that channel A is currently being measured on the upper window.

```
ABOR1
CONFI DEF,3
TRIG1:DEL:AUTO OFF
READ1?
```

**Using INITiate and FETCH?**
The following program segment assumes that channel A is currently being measured on the upper window.

ABOR1
CONFI DEF, 3

Aborts channel A.
Configures the upper window to make a measurement using the current setting of the expected power and source list and a resolution setting of 3.

INIT1

Causes channel A to make a measurement.

FETC1?

Retrieves the upper window's measurement.

Some fine tuning of the above program segment can be carried out for example, by setting the trigger delay off.

ABOR1
CONFI DEF, 3
TRIG1:DEL:AUTO OFF
INIT1: IMM
FETC1?
Example 5 - Making a Difference Measurement

The following program segment can be carried out on the HP EPM-442A. It queries the lower window to make a difference measurement of channel A - channel B. The expected power level and resolution parameters are defaulted, leaving them at their current settings. Some fine tuning of the measurement is carried out by setting the averaging, and the trigger delay to off.

Using READ?

ABOR1

INIT2:IMM
FETCH2:POW:AC:RAT?
FETCH2:POW:AC:RAT? DEF,DEF,(@2),(@1) *(A second FETCH? query is sent to make a channel B - channel A measurement using the current measurement data.)*
Using the Lower Level Commands

An alternative method of making measurements is to use the lower level commands to set up the expected range and resolution. This can be done using the following commands:

\[ \text{SENSe}[1]|\text{SENSe2}:\text{POWER}:\text{AC}:\text{RANGe} \]
\[ \text{DISPLAY}:\text{WINDOW}[1|2]:\text{RESolution} \]

The measurement type can be set using the following commands in the \text{CALCulate} subsystem:

\[ \text{CALCulate}[1|2]:\text{MATH}[:\text{EXPRESSION}] \]
\[ \text{CALCulate}[1|2]:\text{RELative}[:\text{MAGNitude}] \]

The advantage of using the lower level commands over the \text{CONFiGure} command is that they give you more precise control of the power meter. As shown in Table 1-2 on page 1-11, the \text{CONFiGure} command presets various states in the power meter. It may be likely that you do not want to preset these states.

Example

The following example sets the expected power value to -50 dBm and the resolution setting to 3 using the lower level commands. The measurement is a single channel A measurement carried out on the lower window.

\begin{verbatim}
ABOR1
CALC2:MATH:EXPR "(SENS1)"
SENS1:POW:AC:RANG 0
DISP:WIND2:RES 3
INIT1
FETC2?
\end{verbatim}

\begin{itemize}
\item \text{ABOR1} \hspace{1cm} \text{Aborts channel A.}
\item \text{CALC2:MATH:EXPR "(SENS1)"} \hspace{1cm} \text{Displays channel A on lower window.}
\item \text{SENS1:POW:AC:RANG 0} \hspace{1cm} \text{Sets lower range (E-series sensors only).}
\item \text{DISP:WIND2:RES 3} \hspace{1cm} \text{Sets the lower window’s resolution to setting 3.}
\item \text{INIT1} \hspace{1cm} \text{Causes channel A to make a measurement.}
\item \text{FETC2?} \hspace{1cm} \text{Retrieves the lower window’s measurement.}
\end{itemize}
Using Sensor Calibration Tables

This section applies to all HP 8480 series power sensors. It does not apply to the HP E-series power sensors. The HP E-series power sensors have their sensor calibration tables stored in EEPROM which allows frequency and calibration factor data to be downloaded by the power meter automatically.

This section describes how to use sensor calibration tables. Sensor calibration tables are used to store the measurement calibration factors, supplied with each power sensor, in the power meter. These calibration factors are used to correct measurement results.

Overview

For the HP 8480 series power sensors there are two methods of providing correction data to the power meter depending on the setting of the \([\text{SENSe}[1]|\text{SENSe2:CORRection:CSET:STATE}\) command. If \([\text{SENSe}[1]|\text{SENSe2:CORRection:CSET:STATE}\) is OFF the sensor calibration tables are not used. To make a calibrated power measurement when \([\text{SENSe}[1]|\text{SENSe2:CORRection:CSET:STATE}\) is OFF, perform the following steps:

1. Zero and calibrate the power meter. Before carrying out the calibration set the reference calibration factor for the power meter you are using.
2. Set the calibration factor to the value for the frequency of the signal you want to measure.
3. Make the measurement.

When \([\text{SENSe}[1]|\text{SENSe2:CORRection:CSET:STATE}\) is ON, the sensor calibration tables are used, providing you with a quick and convenient method for making power measurements at a range of frequencies using one or more power sensors. Note that with the sensor calibration table selected, the RCF from the table overrides any value previously set. The power meter is capable of storing 20 sensor calibration tables of 80 frequency points each.
Power Meter Remote Operation
Using Sensor Calibration Tables

Figure 1-1 illustrates how sensor calibration tables operate.

**Figure 1-1: Sensor Calibration Tables**

<table>
<thead>
<tr>

<td>CFAC 80</td>
</tr>
</tbody>
</table>

CFAC = Calibration Factor
RCF = Reference Calibration Factor

**TABLE SELECTED**

Reference Calibration Factor used for Power Meter Calibration.

Frequency of the signal you want to measure

Calibration Factor used to make Measurement. Calculated by the Power Meter using linear interpolation.
To use sensor calibration tables you:

1. Edit a sensor calibration table if necessary.
2. Select the sensor calibration table.
3. Enable the sensor calibration table.
4. Zero and calibrate the power meter. The reference calibration factor used during the calibration is automatically set by the power meter from the sensor calibration table.
5. Specify the frequency of the signal you want to measure. The calibration factor is automatically set by the power meter from the sensor calibration table.
6. Make the measurement.
Editing Sensor Calibration Tables

It is not possible to create any additional sensor calibration tables. However, the 20 existing ones can be edited using the MEMory subsystem. To do this:

1. Select one of the existing tables using:
   MEMory:TABLE:SELECT <string>.
   For information on naming sensor calibration tables see "Naming Sensor Calibration Tables", on page 1-33. For information on the current names which you can select refer to "Listing the Sensor Calibration Table Names", on page 1-31.

2. Enter the frequency data using:
   MEMory:TABLE:FREQuency <numeric_value>
   {,<numeric_value>}

3. Enter the calibration factors using:
   MEMory:TABLE:GAIN <numeric_value>
   {,<numeric_value>}. The first parameter you enter should be the reference calibration factor; each subsequent parameter is a calibration factor in the sensor calibration table. This means that entries in the frequency list correspond as shown with entries in the calibration factor list.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Calibration Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reference Calibration Factor</td>
</tr>
<tr>

<tr>
<td>Frequency 2</td>
<td>Calibration Factor 2</td>
</tr>
<tr>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>Frequency n</td>
<td>Calibration Factor n</td>
</tr>
</tbody>
</table>

4. If required, rename the sensor calibration table using:
   MEMory:TABLE:MOVE <string>,<string>. The first <string> parameter identifies the existing table name, and the second identifies the new table name.
Power Meter Remote Operation

Using Sensor Calibration Tables

Note

The legal frequency suffix multipliers are any of the IEEE suffix multipliers, for example, KHz, MHZ and GHZ. If no units are specified the power meter assumes the data is Hz.

PCT is the only legal unit for calibration factors and can be omitted.

The frequency and calibration data must be within range. Refer to the individual commands in Chapter 4 for their specified ranges.

The number of calibration factor points must be one more than the number of frequency points. This is verified when the sensor calibration table is selected using

\[ \text{SENSe1]}\text{SENSe2:CORRection:CSET[:SELECT]} \text{<string>}. \]

Ensure that the frequency points you use cover the frequency range of the signals you want to measure. If you measure a signal with a frequency outside the frequency range defined in the sensor calibration table, then the power meter uses the highest or lowest frequency point in the sensor calibration table to calculate the calibration factor.

To make subsequent editing of a sensor calibration table simpler, it is recommended that you retain a copy of your data in a program.

Listing the Sensor Calibration Table Names

To list the sensor calibration tables currently stored in the power meter, use the following command:

\[ \text{MEMory:CATalog:TABLE?} \]

The power meter returns the data in the form of two numeric parameters and 20 strings representing the stored sensor calibration tables.

- \(<\text{numeric_value}>,<\text{numeric_value}>[,<\text{string}>]\)

  The first numeric parameter indicates the amount of memory, in bytes, used for storage of sensor calibration tables. The second parameter indicates the memory, in bytes, available for sensor calibration tables.
Power Meter Remote Operation
Using Sensor Calibration Tables

Each string parameter returned indicates the name, type and size of a stored sensor calibration table:

- `<string>,<type>,<size>`
  The `<string>`, `<type>` and `<size>` are all character data. The `<type>` is always `TABL`. The `<size>` is displayed in bytes.

For example, a sample of the response may look like:

560,8020,"Sensor_1,TABL,220","Sensor_2,TABL,340" ....

The power meter is shipped with a set of predefined sensor calibration tables. The data in these sensor calibration tables is based on statistical averages for a range of Hewlett-Packard Power Sensors (see Chapter 2, “Editing Sensor Calibration Tables” in the User’s Guide). These power sensors are:

- DEFAULT\(^1\)
- HP 8481A
- HP 8482A\(^2\)
- HP 8483A
- HP 8481D
- HP 8485A
- R8486A
- Q8486A
- R8486D
- HP 8487A

For further information on naming sensor calibration tables see “Naming Sensor Calibration Tables”, on page 1-33.

---

1. DEFAULT is a sensor calibration table in which the reference calibration factor and calibration factors are 100%. This sensor calibration table can be used during the performance testing of the power meter.
2. The HP 8482B and HP 8482H power sensors use the same data as the HP 8482A.
Naming Sensor Calibration Tables

To rename a sensor calibration table use:
MEMory:TABLE:MOVE <string>,<string>

The first <string> parameter identifies the existing table name, and the second identifies the new table name.

The following rules apply to sensor calibration table names:

a) The sensor calibration table must consist of no more than 12 characters.

b) All characters must be upper or lower case alphabetic characters, or numeric (0-9), or an underscore (_).

c) No spaces are allowed in the name.
Power Meter Remote Operation
Using Sensor Calibration Tables

Reviewing Table Data

To review the data stored in a sensor calibration table, use the following commands:

- `MEMORY:TABLE:SELECT "Sense1"
  Select the sensor calibration table named “Sense1”.
- `MEMORY:TABLE:SELECT?
  Query command which returns the name of the currently selected table.
- `MEMORY:TABLE:FREQuency:POINTS?
  Query command which returns the number of stored frequency points.
- `MEMORY:TABLE:FREQuency?
  Query command which returns the frequencies stored in the sensor calibration table (in Hz).
- `MEMORY:TABLE:GAIN[:MAGNitude]:POINTS?
  Query command which returns the number of calibration factor points stored in the sensor calibration table.
- `MEMORY:TABLE:GAIN[:MAGNitude]?
  Query command which returns the calibration factors stored in the sensor calibration table. The first point returned is the reference calibration factor.

Modifying Data

If you need to modify the frequency and calibration factor data stored in a sensor calibration table you need to resend the complete data lists. There are two ways to do this:

1. If you have retained the original data in a program, edit the program and resend the data.
2. Use the query commands shown in “Reviewing Table Data”, on page 1-34 to enter the data into your computer. Edit this data, then resend it.
Selecting a Sensor Calibration Table

After you have created the sensor calibration table, you can select it using the following command:

[SENSe[1]]|SENSe2:CORRection:CSET[:SELect] <string>

When the table is selected, the power meter verifies the number of calibration factor points defined in the sensor calibration table is one parameter greater than the number of frequency points. If this is not the case an error occurs.

To find out which sensor calibration table is currently selected, use the query:

[SENSe[1]]|SENSe2:CORRection:CSET[:SELect]?

Enabling the Sensor Calibration Table System

To enable the sensor calibration table, use the following command:

[SENSe[1]]|SENSe2:CORRection:CSET:STATE ON

If you set [SENSe[1]]|SENSe2:CORRection:CSET:STATE to ON and no sensor calibration table is selected error -221, “Settings conflict” occurs.
Making the Measurement

To make the power measurement, set the power meter for the frequency of the signal you want to measure. The power meter automatically sets the calibration factor. Use either the INITiate, FETCH? or the READ? query to initiate the measurement as shown in the following program segments:

INITiate Example

ABORt1
CONFigure1:POWeR:AC DEF,1,(@1)
SENS1:CORR:CSET:SEL "HP8481A"
SENS1:CORR:CSET:STAT ON
SENS1:FREQuency 500KHZ
INITiate:IMMediate
FETCH1?

READ? Example

ABORt1
CONFigure1:POWeR:AC DEF,2,(@1)
SENS1:CORR:CSET:SEL "HP8481A"
SENS1:CORR:CSET:STAT ON
SENS1:FREQuency 500KHZ
READ1?

Note

If the measurement frequency does not correspond directly to a frequency in the sensor calibration table, the power meter calculates the calibration factor using linear interpolation.

If you enter a frequency outside the frequency range defined in the sensor calibration table, then the power meter uses the highest or lowest frequency point in the sensor calibration table to set the calibration factor.

To find out the value of the calibration factor being used by the power meter to make a measurement, use the query command: [SENSe[1]]|SERNSe2:CORRection:CFAC? The response may be an interpolated value.

To find out the value of the reference calibration factor being used, use the commands: CALibration[1|2]:RCFactor?
Setting the Range, Resolution and Averaging

This section provides an overview of setting the range, resolution and averaging. For more detailed information about these features refer to the individual commands in Chapter 9.

Range

The power meter has no internal ranges which can be set. The only ranges that can be set are those of the HP E-series power sensors. With an HP E-series power sensor the range can be set either automatically or manually. Use autoranging when you are not sure of the power level you will be measuring.

Setting the Range

To set the range manually use the following command:

[SENSe[1]][:SENSe2:POWer:AC:RANGE <numeric_value>]

If the <numeric_value> is set to:

- 0, the sensor’s lower range is selected. (For example, this range is -70 to -13.5 dBm for the HP ECP-18A power sensor.)
- 1, the sensor’s upper range is selected. (For example, this range is -14.5 to +20 dBm for the HP ECP-18A power sensor.)

For details on the range limits of other HP E-series power sensors refer to the appropriate power sensor manual.

For further information on this command refer to page 9-48.

To enable autoranging use the following command:

[SENSe[1]][:SENSe2:POWer:AC:RANGE:AUTO ON]

Use autoranging when you are not sure of the power level you will be measuring.
Resolution

You can set the window’s resolution using the following command:

\texttt{DISPlay[:WINdow\{1\|2\}]:RESolution <numeric\_value>}

There are four levels of resolution available (1 through 4).

When the measurement suffix is W or % this parameter represents the number of significant digits. When the measurement suffix is dB or dBM, 1 through 4 represents 1, 0.1, 0.01, and 0.001 dB respectively.

For further information refer to the resolution command on page 5-14.

Averaging

The power meter has a digital filter to average power readings. The number of readings averaged can range from 1 to 1024 in binary progression. This filter is used to reduce noise, obtain the desired resolution and to reduce the jitter in the measurement results. However, the time to take the measurement is increased. You can select the filter length or you can set the power meter to auto filter mode. To enable and disable averaging use the following command:

\texttt{[SENSe\{1\}]|SENSe2:AVERage[:STATe] <Boolean>}

\underline{Note} \hspace{1cm} If you are using the HP 437B remote programming language you cannot enter a value of 1024.

Auto Averaging Mode

To enable and disable auto filter mode, use the following command:

\texttt{[SENSe\{1\}]|SENSe2:AVERage:COUNT:AUTO <Boolean>}

When the auto filter mode is enabled, the power meter automatically sets the number of readings averaged together to satisfy the filtering requirements for most power measurements. The number of readings averaged together depends on the resolution and the power level currently being measured. Figure 1-2 lists the number of readings averaged for each range and resolution when the power meter is in auto filter mode.
Figure 1-2: Averaged Readings

Figure 1-3 illustrates part of the power sensor dynamic range hysteresis.

Figure 1-3: Averaging Range Hysteresis

Range Hysteresis

Minimum Sensor Power

9.5 dB

Minimum Sensor Power + 10 dB

10.5 dB
Filter Length

You specify the filter length using the following command:

```
[SENSe[1]]:SENSe2:AVERage:COUNT <numeric_value>
```

The range of values for the filter length is 1 to 1024. Specifying this command disables automatic filter length selection. If a numeric parameter is specified which is not a binary multiple, the power meter rounds to the nearest power of two. For example, if you specify a filter length of 5, the power meter rounds the value to 4. Increasing the value of the filter length reduces measurement noise. However, the time to take the measurement is increased.
Setting Offsets

Channel Offsets

The power meter can be configured to compensate for signal loss or gain in your test setup (for example, to compensate for the loss of a 10 dB attenuator). You use the SENSE command subsystem to configure the power meter. Gain and loss correction are a coupled system. This means that a gain set by \([\text{SENSe}[1]]|\text{SENSe2:CORRection:GAIN2}\) is represented in the \([\text{SENSe}[1]]|\text{SENSe2:CORRection:LOSS2}\) command. If you enter an offset value the state is automatically enabled. However, it can be enabled and disabled using either the \([\text{SENSe}[1]]|\text{SENSe2:CORRection:GAIN2:STATE}\) or \([\text{SENSe}[1]]|\text{SENSe2:CORRection:LOSS2:STATE}\) commands.

\(\text{LOSS2}\) is coupled to \(\text{GAIN2}\) by the equation \(\text{Loss} = \frac{1}{\text{Gain}}\) when the default unit is linear, and \(\text{Gain} = -\text{Loss}\) when the default is logarithmic.

Note

You can only use \(\text{LOSS2}\) and \(\text{GAIN2}\) for external losses and gains. \(\text{LOSS1}\) and \(\text{GAIN1}\) are specifically for calibration factors.

Display Offsets

Display offset values can be entered using the \(\text{CALCulate}[1\,2]:\text{GAIN}[:\text{MAGNitude}]\) command. \(\text{CALCulate}[1\,2]:\text{GAIN:STATE}\) must be set to \text{ON} to enable the offset value. If you enter an offset value the state is automatically enabled. On the HP EPM-442A this offset is applied after any math calculations (refer to Figure 1-8 on page 1-58).
Power Meter Remote Operation
Setting Offsets

Example

The following example program, in HP Basic, details how to use the channel and display offsets on an HP EPM-442A making a channel A/B ratio measurement. The final result will be:

\[
\left( \frac{A_{\mathrm{dBm}} - 10}{(B_{\mathrm{dBm}} - 10) - 20} \right)_{\mathrm{dB}}
\]

10 !Create I/O path name
20 ASSIGN @POWER TO 713
30 !Clear the power meter's interface
40 CLEAR @POWER
50 !Set the power meter to a known state
60 OUTPUT @POWER: "*RST"
70 !Configure the Power Meter to make the measurement
80 OUTPUT @Power; "CONF:POW:AC:RAT 20DBM,2,(@1),(@2)"
90 !Set the measurement units to dBm
100 OUTPUT @POWER; "UNIT:POW DBM"
110 !Set the power meter for channel offsets of -10 dB
120 OUTPUT @POWER; "SENS1:CORR:GAIN2 -10"
130 OUTPUT @POWER; "SENS2:CORR:GAIN2 -10"
140 !Enable the gain correction
150 OUTPUT @POWER; "SENS:CORR:GAIN2:STATe ON"
160 OUTPUT @POWER; "SENS2:CORR:GAIN2:STATe ON"
170 !Set the power meter for a display offset of -20 dB
180 OUTPUT @POWER; "CALC1:GAIN -20 DB"
190 PRINT "MAKING THE MEASUREMENT"
200 !Initiate the measurement
210 OUTPUT @Power; "INIT1:IMM"
220 OUTPUT @Power; "INIT2:IMM"
230 !... and get the result
240 OUTPUT @Power; "FETC:POW:AC:RAT? 20DBM,2,(@1),(@2)"
250 ENTER @Power;Reading
260 !
270 PRINT "The measurement result is ";Reading;"dB."
280 END

For further information on channel offsets refer to page 9-23 through page 9-32.
For further information on display offsets refer to page 3-3.
Setting Measurement Limits

The power meter can be configured to verify the power being measured against an upper and/or lower limit value. The range of values that can be set for lower and upper limits is -150.00 dBm to +230.00 dBm. The default upper limit is +90.00 dBm and the default lower limit is -90.00 dBm.

A typical application for this feature is shown in Figure 1-4.

Figure 1-4: Limits Checking Application

![Diagram showing swept source, device under test, and power meter with connections and labels]

Figure 1-5: Limits Checking Results

![Graph showing amplitude and frequency with limits marked]

Fail

HP EPM-441A/442A Programming Guide 1-43
Power Meter Remote Operation
Setting Measurement Limits

In this application a swept frequency signal is applied to the input of the Device Under Test. The power meter measures the output power. The limits have been set at +4 dBm and +10 dBm. A fail occurs each time the output power is outside these limits. Use the SENSE subsystem to configure the power meter for limits checking. The following example program, in HP Basic, shows how to set the limits to +4 dBm and +10 dBm.

10 !Create I/O path name
20 ASSIGN @Power to 713
30 !Clear the Power Meter's Interface
40 CLEAR @Power
50 !Set the Power Meter to a known state
60 OUTPUT @Power;"RST"
70 !Set the measurement units to dBm
80 OUTPUT @Power;"UNIT:POWER DBM"
90 !Set the upper limit to 10 dBm
100 OUTPUT @Power;"SENSe:LIMIT:UPPer 10"
110 !Set the lower limit to 4 dBm
120 OUTPUT @Power;"SENSe:LIMIT:LOWer 4"
130 !Switch the limit checking on
140 OUTPUT @Power;"SENSe:LIMIT:STATE ON"
150 !Check the limits
160 OUTPUT @Power;"SENSe:LIMIT:UPPer?"
170 ENTER @Power;A
180 OUTPUT @Power;"SENSe:LIMIT:LOWer?"
190 ENTER @Power;B
200 PRINT A,B
210 END

Checking for Limit Failures

There are two ways to check for limit failures; using the SENSE:LIMIT:FAIL? and the SENSE:LIMIT:PCount? commands or using the STATUS command subsystem.
Using SENSE

Using SENSE to check the limit failures in Figure 1-5 would return the following results:

SENSe:LIMit:FAIL?  
Returns 1 if there has been 1 or more limit failures or 0 if there have been no limit failures. In this case 1 is returned.

SENSe:LIMit:FCount?  
Returns the total number of limit failures, in this case 2.

Note  
If TRIGger:DELay:AUTO is set to ON, then the number of failures returned by SENSE:LIMit:FCount? will be affected by the current filter settings.

Refer to page 9-40 and page 9-41 for further information on using these commands.

Using STATus

You can use the STATus subsystem to generate an SRQ to interrupt your program when a limit failure occurs. This is a more efficient method than using SENSE, since you do not need to check the limit failures after every power measurement.

Refer to “Status Reporting”, on page 1-59 and “STATus Subsystem”, on page 10-1 for further information.
Measuring Pulsed Signals

The power meter can be used to measure the power of a pulsed signal. The measurement result is a mathematical representation of the pulse power rather than an actual measurement. The power meter measures the average power of the pulsed input signal and then divides the measurement result by the duty cycle value to obtain the pulse power reading. The allowable range of values is 0.001% to 99.999%. The default is 1.000%. A duty cycle value can be set using the following command:

```
[SENSe1] | SENSE2:CORRection:DCYcle|GAIN3 <numeric_value>
```

**Note**

Pulse measurements are not recommended using HP ECP series power sensors.

Making the Measurement

An example of a pulsed signal is shown in Figure 1-6.

**Figure 1-6: Pulsed Signal**

![Pulsed Signal Diagram]

You use the SENSE command subsystem to configure the power meter to measure a pulsed signal. The following example program, in HP Basic, shows how to measure the signal for the HP 8480 series power sensors.
10 !Create I/O path name
20 ASSIGN @Power TO 713
30 !Clear the Power Meter's Interface
40 CLEAR @Power
50 !Set the Power Meter to a known state
60 OUTPUT @Power:""*RST"
70 !Configure the Power Meter to make the measurement
80 OUTPUT @Power:""CONF:POW:AC 20DBM,2,(01)"
90 !Set the reference calibration factor for the sensor
100 OUTPUT @Power:""CAL:RFC 98.7PCT"
110 !Zero and calibrate the power meter
120 OUTPUT @Power:""CAL?"
130 PRINT "ZEROING AND CALIBRATING THE POWER METER"
140 !Verify the outcome
150 ENTER @Power;Success
160 IF Success=0 THEN
170 !Calibration cycle was successful
180 !
190 !Set the measurement units to Watts
200 OUTPUT @Power:""UNIT:POW WATT"
210 !
220 !Set the measurement calibration factor for the sensor
230 OUTPUT @Power:""SENS:CORR:CFMC 97.5PCT"
240 !Set the power meter for a duty cycle of 16PCT
250 OUTPUT @Power:""SENS1:CORR:DCYC 16PCT"
260 !
270 !Enable the duty cycle correction
280 OUTPUT @Power:""SENS:CORR:DCYC:STAT ON"
290 PRINT "MAKING THE MEASUREMENT"
300 !Initiate the measurement
310 OUTPUT @Power:""INIT1:IMM"
320 !... and get the result
330 OUTPUT @Power:""FETOC?"
340 ENTER @Power;Reading
350 !
360 PRINT "The result is ";Reading*1000;"mW"
370 !
380 ELSE
390 PRINT "THERE WAS A CALIBRATION ERROR!"
400 END IF
410 PRINT "PROGRAM COMPLETED"
420 END
Power Meter Remote Operation
Measuring Pulsed Signals

Note

Pulse power averages out any aberrations in the pulse such as overshooting or ringing. For this reason it is called pulse power and not peak power or peak pulse power.

In order to ensure accurate pulse power readings, the input signal must be pulsed with a rectangular pulse. Other pulse shapes (such as triangle, chirp or Gaussian) will cause erroneous results.

The pulse power on/off ratio must be much greater than the duty cycle ratio.
Triggering the Power Meter

Triggering is a feature that is only available via remote programming of the power meter.

The power meter has two modes of operation, standby mode and free run mode. During local operation the power meter is always in free run mode. During remote operation the power meter can operate in either free run mode or standby mode and can be switched between modes at any time.

a) Standby mode means the power meter is making measurements, but the display and HP-IB are not updated until a trigger command is received.
In this mode the power meter is either waiting to be initiated, or waiting for a trigger (See “Trigger System” on page 51.).

b) Free run mode is the preset mode of operation and is identical to local operation. The measurement result data available to the HP-IB is continuously updated as rapidly as the power meter makes measurements. Entry into local mode via [Local] sets the power meter to free run mode.
In this mode INITiate:CONTinuous is set to ON and TRIGger:SOURce is set to IMMEDIATE.

To obtain accurate measurements, ensure that the input power to the power sensor is settled before making a measurement.

The trigger configuration is automatically set by the MEASURE? command. If you want to use the lower level commands (READ? or INITiate), you need to understand the power meter's trigger model.
Power Meter Remote Operation

Triggering the Power Meter

Triggering the power meter from the remote interface is a process that offers triggering flexibility. The process is:

1. Specify the source from which the power meter will accept the trigger. The trigger source specifies which event causes the trigger system to travel through the event detection state. See “Event Detection State”, on page 1-52 for details.

2. Make sure that the power meter is ready to accept a trigger. This is called the “wait-for-trigger” state. Sending a device clear, a *RST or an ABORT forces the trigger system into the idle state. The trigger system remains in the idle state until it is moved into the “wait-for-trigger” state by executing an INITiate command.

The “wait-for-trigger” state is a term used only for remote interface operation.

The TRIGGER commands are used to synchronize power meter actions with specified events. Figure 1-7 summarizes the power meter’s trigger system.
Figure 1-7: Trigger System

Idle State

Turning power on, sending an HP-IB CLEAR, sending a *RST or an :ABORt forces the trigger system into the idle state. The trigger system remains in the IDLE state until it is initiated by INITiate:CONTinuous ON or INITiate:IMMediate. Once one of these conditions is satisfied the trigger system moves to the initiate state.
Power Meter Remote Operation
Triggering the Power Meter

Initiate State
If the trigger system is on the downward path, it travels directly through the initiate state without any restrictions. If the trigger system is on the upward path, and INITiate:CONTinuous is ON, it exits downwards to the event detection state. If the trigger system is on the upward path and INITiate:CONTinuous is OFF, it exits upwards to the idle state.

Event Detection State
The trigger source specifies which event causes the trigger system to travel through the event detection state. The trigger source is set with the following command:

```
TRIGGER:SOURce
```

There are three possible trigger sources.

- **BUS**
  The trigger source is the HP-IB group execute trigger (<GET>), a *TRG command, or the TRIGGER:IMMEDIATE command.

- **HOLD**
  Triggering is suspended. The only way to trigger the power meter is to send TRIGGER:IMMEDIATE.

- **IMMEDIATE**
  The power meter does not wait for any event and immediately travels through the event detection state.

Querying the Trigger Source
The trigger source is queried with the following command:

```
TRIGGER:SOURce
```
Trigger Delay

The power meter has the ability to insert a delay between receiving a trigger and making the measurement. The delay is automatically calculated by the power meter and depends on the current filter length. The delay ensures that the analog circuitry and the digital filters in the power meter have settled. It does not allow time for power sensor delay.

To enable the delay, use the following command:

TRIGger:DELay:AUTO ON

To disable the delay, use the following command:

TRIGger:DELay:AUTO OFF

---

Note  
MEASURE? and CONFIGure automatically enable the delay. Also, when the power meter is first powered on the delay is enabled. For the fastest possible measurements the delay should be disabled.
Getting the Best Speed Performance

This section discusses the factors that influence the speed of operation (number of readings/sec) of an HP EPM-441/2A power meter.

The following factors are those which have the greatest effect upon measurement speed (in no particular order):

- The selected speed i.e. 20, 40 or 200 readings/sec.
- The trigger mode (for example, free run, trigger with delay etc.).
- The output format i.e. ASCII or REAL.
- The units used for the measurement.
- The command used to take a measurement.

In addition, in 200 reading/sec mode there are other influences which are described in “200 Readings/Sec”, on page 1-56.

The following paragraphs give a brief description of the above factors and how they are controlled from SCPI.

Speed

There are three possible speed settings 20, 40 and 200 readings/sec. These are set using the SENSE:SPEED command and can be applied to each channel independently (HP EPM-442A only). The speed setting controls the cycle time of the measurement i.e., 50ms, 25ms and 5ms respectively.

In 20 and 40 readings/sec mode, full instrument functionality is available; 200 readings/sec is available only for E-series sensors and averaging, offsets, limits, and ratio/difference math functions are disabled.

Refer to “Specifications” in chapter 5 of the User’s Guide to see the influence of these speed settings on the accuracy and noise performance of the power meter.

Trigger Mode

The power meter has a very flexible triggering system. For simplicity, it can be described as having three modes:
Free run

A channel is in free run when INITiate:CONTinuous is set to ON and TRIGger:SOURce is set to IMMEDIATE.

Trigger immediate

There are a variety of methods to achieve this:

- TRIG:DEL:AUTO OFF
- INIT:CONT OFF
- TRIG:SOUR IMM
- INIT

- TRIG:SOUR BUS
- INIT:CONT ON
- TRIG

- TRIG:DEL:AUTO OFF
- TRIG:SOUR BUS
- INIT:CONT ON
- GET or *TRG

- TRIG:DEL:AUTO OFF
- INIT:CONT OFF
- TRIG:SOUR IMM
- READ?

Trigger with delay

This can be achieved using the same sequences above (apart from the second) with TRIG:DEL:AUTO set to ON. Also, the MEAS? command operates in trigger with delay mode.

In trigger with delay mode, a measurement is not completed until the power meter filter is full. In this way, the reading returned is guaranteed to be settled. In all other modes, the result returned is simply the current result from the filter and may or may not be settled. This depends on the current length of the filter and the number of readings that have been taken since a change in power level.

With trigger with delay enabled, the measurement speed can be calculated roughly using the following equation:

\[
\text{readings/sec} = \text{speed (as set by SENSE:SPEED)} / \text{filter length}
\]
Power Meter Remote Operation
Getting the Best Speed Performance

For example, with a filter length of 4 and SENS: SPE set to 20, approximately 5 readings/seg will be calculated by the power meter.

In general, free run mode will provide the best speed performance from the power meter (especially in 200 readings/sec mode).

Output Format

The power meter has two output formats for measurement results: ASCII and REAL. These formats can be selected using the FORMAT command. When FORMAT is set to REAL, the result returned is in IEEE 754 floating-point format (note that the byte order can be changed using FORMAT:BORDER).

The REAL format is likely to be required only for 200 readings/sec mode as a means to reduce bus traffic.

Units

The power meter can output results in either linear or log units. The internal units are linear and therefore optimal performance will be achieved when the results output are also in linear units (since the overhead of performing a log function is removed).

Command Used

In free run trigger mode, FETCH? must be used to retrieve a result.

In other trigger modes, there are a number of commands which can be used, for example, MEAS?, READ?, FETCH? Note that the MEAS? and READ? commands are compound commands i.e., they perform a combination of other lower level commands. In general, the best speed performance will be achieved using the low level commands directly.

200 Readings/Sec

In the highest speed setting, the limiting factor tends to be the speed of the controller being used to retrieve results from the power meter and to a certain extent the volume of HP-IB traffic. The latter can be reduced using the FORMAT REAL command to return results in binary format. The former is a combination of two factors:
the hardware platform being used.
the programming environment being used.

Note that it is unlikely that 200 readings/sec can be achieved when:

- you are using a 700 series HPUX workstation.
- you are using a low end PC.
- you are using a graphical programming environment (such as HP VEE).

**Dual Channel Considerations**

With the dual channel instrument, consideration must be taken of what operation is required on both channels. Both channels can achieve 20 readings/sec simultaneously, and 40 readings/sec simultaneously, but 200 readings/sec is not achievable on both channels at the same time. If only single channel measurements are required, then the other channel should be set to standby mode and not triggered.

The throughput for a channel set in the 200 readings/sec mode will be affected by the speed mode of the other channel. However, in a situation where fast measurements are required on one channel and slow measurements on the other, it will be possible to perform more than one measurement cycle on the fast channel for every measurement on the slow channel. For example, if channel A is set to 40 readings/sec and channel B is set to 20 readings/sec, it is possible to construct a loop with 2 reads from channel A and one from channel B and still achieve the set readings per second.
How Measurements are Calculated

Figure 1-8 details how measurements are calculated. It shows the order in which the various power meter functions are implemented in the measurement calculation.

Figure 1-8: How Measurements are Calculated

The MEASure commands in this figure can be replaced with the FETCH? and READ? commands.

Note

All references to channel B in the above diagram refer to the HP EPM-442A only. The MEAS[1|2]:POW:AC? and MEAS[1|2]:POW:AC:REL? are the only commands relevant to the HP EPM-441A.
Each of the 16-bit status groups consists of 5 registers as shown on page 1-60.
Status Reporting

Status reporting is used to monitor the power meter to determine when events have occurred. Status reporting is accomplished by configuring and reading status registers. The power meter has the following main registers:

- Status Register
- Standard Event Register
- Operation Status Register
- Questionable Status Register
- Device Status Register

There are a number of other registers “behind” these. These are described later.

The Status and Standard Event registers are read using the IEEE-488.2 common commands. These are the most commonly used registers and are described in detail in this section.

The Operation and Questionable Status registers are read using the SCPI \texttt{STATUS} command subsystem.
The General Status Register Model

The generalized status register model shown in Figure 1-9 is the building block of the SCPI status system. This model consists of a condition register, a transition filter, an event register and an enable register. A set of these registers is called a status group.

Figure 1-9: Generalized Status Register Model

When a status group is implemented in an instrument, it always contains all of the component registers. However, there is not always a corresponding command to read or write to every register.

Condition Register

The condition register continuously monitors the hardware and firmware status of the power meter. There is no latching or buffering for this register, it is updated in real time. Condition registers are read-only.

Transition Filter

The transition filter specifies which types of bit state changes in the condition registers will set corresponding bits in the event register. Transition filter bits may be set for positive transitions (PTR), negative transitions (NTR), or both. Transition filters are read-write. They are unaffected by *CLS or queries. After STATUS:PRESet the NTR register is set to 0 and all bits of the PTR are set to 1.

Event Register

The event register latches transition events from the condition register as specified by the transition filter. Bits in the event register are latched and once set they remain set until cleared by a query or a *CLS. Once set, an event bit is no longer affected by condition changes. It remains set until the event register is cleared; either when you read the register or when you send the *CLS (clear status) command. Event registers are read-only.
Enable Register

The enable register specifies the bits in the event register that can generate a summary bit. The instrument logically ANDs corresponding bits in the event and enable registers and ORs all the resulting bits to obtain a summary bit. Enable registers are read-write. Querying an enable register does not affect it.

An Example Sequence

Figure 1-10 illustrates the response of a single bit position in a typical status group for various settings. The changing state of the condition in question is shown at the bottom of the figure. A small binary table shows the state of the chosen bit in each status register at the selected times T1 to T5.

Power Meter Remote Operation
Status Reporting

How to Use Registers

There are two methods you can use to access the information in status groups:

- the polling method, or
- the service request (SRQ) method.

Use the polling method when:

- your language/development environment does not support SRQ interrupts.
- you want to write a simple, single purpose program and do not want to add the complexity of setting an SRQ handler.

Use the SRQ method when you:

- need time critical notification of changes.
- are monitoring more than one device which supports SRQ interrupts.
- need to have the controller do something else while it's waiting.
- cannot afford the performance penalty inherent to polling.
The Condition Polling Method

In this polling method, the power meter has a passive role. It only informs the controller that conditions have changed when the controller asks. When you monitor a condition with the polling method, you must:

1. Determine which register contains the bit that monitors the condition.
2. Send the unique HP-IB query that reads that register.
3. Examine the bit to see if the condition has changed.

The polling method works well if you do not need to know about the changes the moment they occur. The SRQ method is more effective if you must know immediately when a condition changes. Detecting an immediate change in a condition using the polling method requires your program to continuously read the registers at very short intervals. This is not particularly efficient and there is a possibility that an event may be missed.
Power Meter Remote Operation
Status Reporting

The SRQ Method

When a bit of the Status Register is set and has been enabled to assert SRQ (*SRE command), the power meter sets the HP-IB SRQ line true. This interrupt can be used to interrupt your program to suspend its current operation and find out what service the power meter requires. (Refer to your computer and language manuals for information on how to program the computer to respond to the interrupt).

To allow any of the Status Register bits to set the SRQ line true, you have to enable the appropriate bit(s) with the *SRE command. For example, suppose your application requires an interrupt whenever a message is available in the output queue (Status Register bit 4, decimal weight 16). To enable bit 4 to assert SRQ, you use the following command:

*SRE 16

Note

You can determine which bits are enabled in the Status Register using *SRE?. This command returns the decimal weighted sum of all the bits.

Procedure

- Send a bus device clear message.
- Clear the event registers with the *CLS (clear status) command.
- Set the *ESE (standard event register) and *SRE (status byte register) enable masks.
- Enable your bus controller's IEEE-488 SRQ interrupt.

Examples

The following two examples are written in HP BASIC and illustrate possible uses for SRQ. In both cases, it is assumed that the meter has been zeroed and calibrated.

Example 1:

10 ! Program to generate an SRQ when a channel A sensor
20 ! connect or disconnect occurs
30 !
40 ASSIGN @Pm TO 713 ! Power meter HPIB address
50 ON ON INTR 7 GOTO Srq_1! Define service request handler
60 CLEAR @Pm ! Selective device clear
70 OUTPUT @Pm;**CLS;*RST* ! Clear registers and reset meter
80 !

1-64 HP EPM-441A/442A Programming Guide
! Configure the device status register so that a sensor
! connect or disconnect on channel A will cause an SRQ.
!
OUTPUT @Pm;"STAT:DEV:ENAB 2"
OUTPUT @Pm;"STAT:DEV:NTR 2"
OUTPUT @Pm;"STAT:DEV:PTR 2"
OUTPUT @Pm;"**SRE 2"
!
ENABLE INTR 7;2 ! Enable an SRQ to cause an interrupt
LOOP ! Idle loop
! Forever
END LOOP
!
! When a SRQ is detected, the following routine will
! service it.
!
SrQ_i: !
St=SPOLL(@Pm) ! Serial Poll (reads status byte)
IF BIT(St,1)=1 THEN ! Device status reg bit set?
OUTPUT @Pm;"STAT:DEV:EVEN?" ! Yes, read register
ENTER @Pm;Event ! (this also clears it)
OUTPUT @Pm;"STAT:DEV:COND?"
Enter @Pm;Cond
IF Cond=0 THEN
PRINT "Sensor disconnected"
ELSE
PRINT "Sensor connected"
END IF
END IF
GOTO 170 ! Return to idle loop
END

Example 2:

! Program to generate an SRQ when an over limit
! condition occurs.
!
ASSIGN @Pm TO 713 ! Power meter HPIB address
ON INTR 7 GOTO SrQ_i ! Define service request handler
CLEAR @Pm ! Selective device clear
OUTPUT @Pm;"**CLS" ! Clear registers
OUTPUT @Pm;"SYST:PRES" ! Preset meter
!
Power Meter Remote Operation

210 ! Forever
220 END LOOP
230 !
240 ! When a SRQ is detected, the following routine will service it.
250 !
260 Src=SPOLL(@Pm) ! Serial Poll (reads status byte)
270 IF BIT(Sr,7)=1 THEN ! Operation status bit set?
280 OUTPUT @Pm;"STAT:OPER?"! Yes, read register
290 ENTER @Pm;Oper ! (this also clears it)
300 OUTPUT @Pm;"STAT:OPER:ULP?"
310 ENTER @Pm;Ulf
320 IF Ulf=2 THEN PRINT "Over limit detected"
340 END IF
350 GOTO 190 ! Return to idle loop
360 END
Status Register

The Status System in the power meter is shown in Figure 1-11. The Operation Status and Questionable Status groups are 16 bits wide, while the Status Byte and Standard Event groups are 8 bits wide. In all 16-bit groups, the most significant bit (bit 15) is not used and is always set to 0.

Figure 1-11: Status System
The Status Byte

The status byte summary register reports conditions from other status registers. Query data waiting in the power meter's output buffer is immediately reported through the “message available” bit (bit 4). Clearing an event register clears the corresponding bits in the status byte summary register. Reading all messages in the output buffer, including any pending queries, clears the message available bit.

</tbody>
</table>
Power Meter Remote Operation

Status Reporting

Particular bits in the status byte register are cleared when:

- The standard event, Questionable status, operation status and device status are queried.
- The error/event queue becomes empty.
- The output queue becomes empty.

The status byte enable register (SRE, service request enable) is cleared when you:

- cycle the instrument power.
- execute a *SRE 0 command.

Using *STB? to Read the Status Byte

The *STB? (status byte query) command is similar to a serial poll except it is processed like any other power meter command. The *STB? command returns the same result as an IEEE-488 serial poll except that the request service bit (bit 6) is not cleared if a serial poll has occurred. The *STB? command is not handled automatically by the IEEE-488 bus interface hardware and the command will be executed only after previous commands have completed. Using the *STB? command does not clear the status byte summary register.

The Standard Event Register

The standard event register reports the following types of instrument events: power-on detected, command and syntax errors, command execution errors, self-test or calibration errors, query errors, or when an overlapped command completes following a *OPC command. Any or all of these conditions can be reported in the standard event summary bit through the enable register. You must write a decimal value using the *ESE (event status enable) command to set the enable register mask.
<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Value</th>
<th>Definition</th>
</tr>
</thead>
</table>
| 0          | 1             | Operation Complete  
All overlapped commands following an *OPC command have been completed. |
| 1          | 2             | Not Used. (Always set to 0.) |
| 2          | 4             | Query Error  
A query error occurred, refer to error numbers 410 to 440 in the User’s Guide. |
| 3          | 8             | Device Error  
A device error occurred, refer to error numbers 310 to 350 in the User’s Guide. |
| 4          | 16            | Execution Error  
An execution error occurred, refer to error numbers 211 to 241 in the User’s Guide. |
| 5          | 32            | Command Error  
A command syntax error occurred, refer to error numbers 101 to 161 in the User’s Guide. |
| 6          | 64            | Not Used. (Always set to 0.) |
| 7          | 128           | Power On  
Power has been turned off and on since the last time the event register was read or cleared. |

The standard event register is cleared when you:

- send a *CLS (clear status) command.
- query the event register using the *ESR? (event status register) command.

The standard event enable register is cleared when you:

- cycle the instrument power.
- execute a *ESE 0 command.
Power Meter Remote Operation

Status Reporting

**Questionable Status Register**

The questionable status register provides information about the quality of the power meter's measurement results. Any or all of these conditions can be reported in the questionable data summary bit through the enable register. You must write a value using the `STATUS:QUESTIONable:ENABLE` command to set the enable register mask.

The questionable status model is shown in the pullout at the end of this chapter.

The following bits in these registers are used by the power meter:

<table>

</tr>
</tbody>
</table>
Using the Operation Complete Commands

The *OPC? and *OPC commands allow you to maintain synchronization between the computer and the power meter. The *OPC? query command places an ASCII character 1 into the power meter's output queue when all pending power meter commands are complete. If your program reads this response before continuing program execution, you can ensure synchronization between one or more instruments and the computer.

The *OPC command sets bit 0 (Operation Complete) in the Standard Event Status Register when all pending power meter operations are complete. By enabling this bit to be reflected in the Status Register, you can ensure synchronization using the HP-IB serial poll.

Procedure

- Send a device clear message to clear the power meter's output buffer.
- Clear the event registers with the *CLS (clear status) command.
- Enable operation complete using the *ESE 1 command (standard event register).
- Send the *OPC? (operation complete query) command and enter the result to assure synchronization.
- Send your programming command string, and place the *OPC (operation complete) command as the last command.
- Use a serial poll to check to see when bit 5 (standard event) is set in the status byte summary register. You could also configure the power meter for an SRQ interrupt by sending *SRE 32 (status byte enable register, bit 5).
Examples

This example program uses the *OPC? command to determine when the power meter has finished calibrating.

CAL: AUTO ONCE
*OPC?
MEAS: POW: AC?

This example program, in HP Basic, uses the *OPC command and serial poll to determine when the power meter has finished calibrating. The advantage to using this method over the *OPC? command is that the computer can perform other operations while it is waiting for the power meter to finish calibrating.

10 ASSIGN @Power TO 713
20 OUTPUT @Power;"*CLS"
30 OUTPUT @Power;"*ESE 1"
40 OUTPUT @Power;"CAL:AUTO ONCE:*OPC"
50 WHILE NOT BIT(SPOLL(@Power),5)
60 !(Computer carries out other operations here)
70 END WHILE
80 OUTPUT @Power;"MEAS: POW: AC?"
90 ENTER @Power;Result
100 PRINT Result
110 END
Saving and Recalling Power Meter Configurations

To reduce repeated programming, up to ten power meter configurations can be stored in the power meter's non-volatile memory. The error list, HP-IB address, programming language, sensor calibration table data, zeroing and calibration information are not stored.

How to Save and Recall a Configuration

Power meter configurations are saved and recalled with the following commands:

*SAV <NRF>
*RCL <NRF>

The range of values for <NRF> in the above commands is 1 to 10.

Example Program

10 ASSIGN @POWER TO 713
20 !Configure the power meter
30 OUTPUT @POWER;"UNIT:POW W"
40 OUTPUT @POWER;"SENS:CORR:LOSS2 -10"
50 OUTPUT @POWER;"SENS:CORR:LOSS2:STAT ON"
60 !Save the configuration
70 OUTPUT @POWER;"*SAV 5"
80 PRINT "Configuration Saved"
90 !Now reset the power meter
100 OUTPUT @POWER;"*RST"
110 !Recall the configuration
120 OUTPUT @POWER;"*RCL 5"
130 PRINT "Configuration Recalled"
140 PRINT "Save and Recall complete"
150 END
Using Device Clear to Halt Measurements

Device clear is an IEEE-488 low-level bus message which can be used to halt measurements in progress. Different programming languages and IEEE-488 interface cards provide access to this capability through their own unique commands. The status registers, the error queue, and all configuration states are left unchanged when a device clear message is received. Device clear performs the following actions.

- All measurements in progress are aborted.
- The power meter returns to the trigger “idle state”.
- The power meter’s input and output buffers are cleared.
- The power meter is prepared to accept a new command string.
An Introduction to the SCPI Language

Standard Commands for Programmable Instruments (SCPI) defines how you communicate with an instrument from a bus controller. The SCPI language uses a hierarchical structure similar to the file systems used by many bus controllers. The command tree is organized with root-level commands (also called subsystems) positioned at the top, with multiple levels below each root-level command. You must specify the complete path to execute the individual lower-level commands.

```
  "A" Subsystem
    :D :E :F

  "B" Subsystem
    :G :H :I
      :J :K :L=:\r\n
  "C" Subsystem
    :M :N=:B:H:N
```

Mnemonic Forms

Each keyword has both a long and a short form. A standard notation is used to differentiate the short form keyword from the long form keyword. The long form of the keyword is shown, with the short form portion shown in uppercase characters, and the rest of the keyword shown in lowercase characters. For example, the short form of TRIGger is TRIG.

Using a Colon (:\)

When a colon is the first character of a command keyword, it indicates that the next command mnemonic is a root-level command. When a colon is inserted between two command mnemonics, the colon moves the path down one level in the present path (for the specified root-level command) of the command tree. You must separate command mnemonics from each other using a colon. You can omit the leading colon if the command is the first of a new program line.
Using a Semicolon (;)

Use a semicolon to separate two commands within the same command string. The semicolon does not change the present path specified. For example, the following two statements are equivalent. Note that in the first statement the first colon is optional but the third is compulsory.

`:DISP:FORM DIG; :DISP:RES 2
`:DISP:FORM DIG; RES 2

Using a Comma (,)

If a command requires more than one parameter, you must separate adjacent parameters using a comma.

Using Whitespace

You must use whitespace characters, [tab], or [space] to separate a parameter from a command keyword. Whitespace characters are generally ignored only in parameter lists.

Using “?” Commands

The bus controller may send commands at any time, but a SCPI instrument may only send responses when specifically instructed to do so. Only query commands (commands that end with a “?”) will instruct the instrument to send a response message. Queries return either measured values or internal instrument settings.

Note

If you send two query commands without reading the response from the first, then attempt to read the second response, you may receive some data from the first response followed by the complete second response. To avoid this, do not send a query command without reading the response. When you cannot avoid this situation, send a device clear before sending the second query command.

Using “*” Commands

Commands starting with a “*” are called common commands. They are required to perform the identical function for all instruments that are compliant with the IEEE-488.2 interface standard. The “*” commands are used to control reset, self-test, and status operations in the power meter.
Power Meter Remote Operation
An Introduction to the SCPI Language

Syntax Conventions
Throughout this guide, the following conventions are used for SCPI command syntax.

- Square brackets ([ ]) indicate optional keywords or parameters.
- Braces ({} ) enclose one or more parameters that may be included zero or more times.
- Triangle brackets (<>) indicate that you must substitute a value for the enclosed parameter.
- Bars (|) can be read as “or” and are used to separate alternative parameter options.

Syntax Diagram Conventions

- Solid lines represent the recommended path.
- Ovals enclose command mnemonics. The command mnemonic must be entered exactly as shown.
- Dotted lines indicate an optional path for bypassing secondary keywords.
- Arrows and curved intersections indicate command path direction.

SCPI Data Types
The SCPI language defines different data formats for use in program messages and response messages. Instruments are flexible listeners and can accept commands and parameters in various formats. However, SCPI instruments are precise talkers. This means that SCPI instruments always respond to a particular query in a predefined, rigid format.

<Boolean> Definition
Throughout this chapter <Boolean> is used to represent ON|OFF|<NRF>. Boolean parameters have a value of 0 or 1 and are unitless. ON corresponds to 1 and OFF corresponds to 0.

On input, an <NRF> is rounded to an integer. A nonzero result is interpreted as 1.

Queries always return a 1 or 0, never ON or OFF.
<character response data> Definition

Throughout this chapter <character_data> is used to represent character data, that is, A - Z, a - z, 0 - 9 and _ (underscore). For example: START and R6_5F. The format is defined as:

<upper-case alpha>

<digit>

<NAN> Definition

Not a number (NAN) is represented as 9.91E37. Not a number is defined in IEEE 754.
<non-decimal numeric>

Throughout this chapter <non-decimal numeric> is used to represent numeric information in bases other than ten (that is, hexadecimal, octal and binary). The following syntax diagram shows the standard for these three data structures. For example, #HA2F, #ha4e, #Q62, #q15, #B01011.

Refer to section 7.7.4.1 of IEEE 488.2 for further details.
<NR1> Definition
Throughout this chapter <NR1> is used to denote a flexible numeric representation. For example: +200; -56; +9.9E36. Refer to section 7.7.2.1 of IEEE 488.2 for further details.

<NR1> Definition
Throughout this chapter <NR1> numeric response data is defined as:

For example:
- 146
- +146
- -12345

Refer to section 8.7.2 of IEEE 488.2 for further details.

<NR2> Definition
Throughout this chapter <NR2> numeric response data is defined as:

For example:
- 12.3
- +1.2345
- -0.123

Refer to section 8.7.3 of IEEE 488.2 for further details.
<NR3> Definition

Throughout this chapter <NR3> numeric response data is defined as:

For example:
- 1.23E+6
- 123.4E-54
- -1234.567E+90.

Refer to section 8.7.4 of IEEE 488.2 for further details.

<numerical value> Definition

Throughout this chapter the decimal numeric element is abbreviated to <numerical value>. For example, <NRf>, MINimum, MAXimum, DEFault or Not A Number (NAN).
<string> Definition

Throughout this chapter <string> is used to represent 7-bit ASCII characters.

The format is defined as:

**Program Data**

```
<inserted '>
<non-single quote char>

<inserted ">
<non-double quote char>
```

**Response Data**

```
<inserted ">
<non-double quote char>
```
Input Message Terminators

Program messages sent to a SCPI instrument must terminate with a <newline> character. The IEEE.488 EOI (end or identify) signal is interpreted as a <newline> character and may also be used to terminate a message in place of the <newline> character. A <carriage return> followed by a <newline> is also accepted. Many programming languages allow you to specify a message terminator character or EOI state to be automatically sent with each bus transaction. Message termination always sets the current path back to the root-level.
Quick Reference

Note
This Guide details the commands available for both the HP EPM-441A and the HP EPM-442A power meters. As the HP EPM-441A is a single channel power meter only channel A can be selected. Where instances of channel selection are detailed in this chapter they are only relevant for the HP EPM-442A.

This section summarizes the SCPI (Standard Commands for Programmable Instruments) commands available to program the power meter. All the commands listed also have queries unless otherwise stated in the “Notes” column. Refer to later chapters for more details on each command.

In different subsystems the numeric suffix of program mnemonics can represent either a channel selection or a window selection. Refer to the appropriate command description to verify the meaning of the numeric suffix.

With commands that require you to specify a channel, Channel A is represented by a 1 and Channel B by a 2. If you omit the channel number, Channel A is assumed.

With commands that require you to specify a window, the upper window is represented by a 1 and the lower window by a 2. If you omit the window number, the upper window is assumed.

STATus Subsystem

As the status reporting commands are orthogonal, the same commands apply to all the registers. The registers are:

STATus:DEVICE
STATus:OPERation
STATus:OPERation:CALibrating[:SUMMary]
STATus:OPERation:LLFail[:SUMMary]
STATus:OPERation:MEAsuring[:SUMMary]
STATus:OPERation:SENSe[:SUMMary]
STATus:OPERation:TRIGger[:SUMMary]
STATus:OPERation:ULFail[:SUMMary]
STATus:QUESTionable
STATus:QUESTionable:CALibration[:SUMMary]
STATus:QUESTionable:POWER[:SUMMary]

The following five commands operate on each of these registers. However, to avoid duplication they are only listed once.

SCPI Compliance Information

The power meter complies with the rules and regulations of the present version of SCPI (Standard Commands for Programmable Instruments). You can determine the SCPI version with which the power meter's is in compliance by sending the SYSTEM:VERSION? command from the remote interface.

The following commands are device-specific to the HP EPM-441A/442A. They are not included in the 1996.0 version of the SCPI standard. However, these commands are designed with the SCPI format in mind and they follow all of the syntax rules of the standard.

UNIT[1|2]:POWer:RATio
The purpose of the MEASure group of instructions is to acquire data using a set of high level instructions.

The MEASure group of commands are structured to allow you to trade off interchangeability with fine control of the measurement process. MEASure? provides a complete capability where the power meter is configured, a measurement taken, and results returned in one operation. Often, more precise control of the measurement is required. Therefore, MEASure? is complemented by providing two commands, CONFigure and READ?. CONFigure performs the configuration portion of the measurement and READ? performs the data acquisition, postprocessing, and data output portions of the measurement. This allows you to perform a generic configuration of the measurement through CONFigure and then customize the measurement by changing particular power meter functions. The READ? then completes the measurement process.

READ?, in turn, is broken down into two additional commands, INITiate[:ImMediate] and FETCH?. INITiate[:ImMediate] performs the data acquisition. FETCH? performs the postprocessing function and returns the data. This allows you to perform several different FETCH? functions on a single set of acquired data.

The HP EPM-441A/442A power meters have several command extensions to the SCPI standard. These are the RELative and DIFFerence nodes.

The numeric suffixes of the CONFigure, FETCH, READ and MEASure? program mnemonics in the MEASure group of commands refers to windows, that is CONFigure1 and CONFigure2 represent the upper and lower windows respectively.
The Optional Parameters

All the MEASure commands have three optional parameters, an expected power value, a resolution and a source list.

Entering an <expected_value> parameter is only relevant if you are using an HP E-series power sensor. With HP 8480 series power sensors entering a value has no effect on the power meter. The value entered determines which of the power sensor's two ranges is used for the measurement. If the current setting of the power sensor's range is no longer valid for the new measurement, specifying the expected power value decreases the time taken to obtain a result.

The <resolution> parameter is used to set the resolution of the specified window. This parameter does not affect the resolution of the HP-IB data, however it does affect the auto averaging setting (refer to Figure 1-2 on page 1-39). In the case where a channel is set up in both the upper and lower window and the <resolution> parameter settings for these windows are different, the highest resolution setting is taken to calculate the averaging. If you are making a ratio or difference measurement the <resolution> parameters are applied to both channels.

The <source list> parameter is used to define:

- in a single channel measurement, what channel the measurement is to be made on.
- in a difference measurement whether the calculation is channel A-B or B-A.
- in a ratio measurement whether the calculation is A/B or B/A.

Entering a <source list> is only relevant if you are using an HP EPM-442A. As the HP EPM-441A only has a single channel the source list can only be channel A.
The commands associated with the **MEASure** group are:

CONFigure[12]

This query returns the present configuration of the specified window.

**Syntax**

![Diagram of syntax]

The string returned depends on the setting of the CALCulate:MATH and CALCulate:RELative:STATe commands.

The configuration is returned as a quoted string in the following format:

"<function> <expected_value>,<resolution>,<source list>"

<table>
<thead>

</tbody>
</table>

---

1. HP EPM-442A only.

<expected_value> returns the expected value sent by the last CONFIGure command or ±20 dBm by default. Note that when the display is showing dual windows this value is meaningless.

The <resolution> returned is the same as the value returned by DISPlay:WINdow:RESolution?. The format of the return is <NRd> in the range 1 through 4.

---

2-6   HP EPM-441A/442A Programming Guide
Example

```
CONF2?
```

This command queries the current configuration of the lower window.

Reset Condition

On reset,

- the command function is set to :POWer:AC.
- the expected power level is set to +20 dBm.
- the resolution is set to 3.
- the source list
  - on the HP EPM-441A is set to channel A on both windows.
  - on the HP EPM-442A is set to channel A on the upper window and channel B on the lower window.
CONFigure[1|2] Commands

The CONFigure commands are used on the specified window to set,

- the expected power level value of the measurement.
- the resolution of the window.
- the channel(s) on which the measurement is to be made.

The CONFigure commands do not make the power measurement after setting the configuration. Use READ?, or alternatively use INITiate followed by a FETCH? to make the measurement.

The CONFigure command also does the following to the channel(s) which are in the specified window (the channel(s) in the window are specified in the <source list> parameter):

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITiate:CONTinuous OFF</td>
<td>Sets the power meter to make one trigger cycle when INITiate is sent.</td>
</tr>
<tr>
<td>TRIGger:SOURce IMMEDIATE</td>
<td>Sets the power meter to make the measurement immediately a trigger is received.</td>
</tr>
<tr>
<td>TRIGger:DELAY:AUTO ON</td>
<td>Enables automatic delay before making the measurement.</td>
</tr>
<tr>
<td>SENSE:AVERAGE:STATE ON</td>
<td>Enables averaging.</td>
</tr>
</tbody>
</table>
MEASurement Instructions
CONFigure[1|2][:SCALar][:POWer:AC] [<expected_value>,<resolution>,<source list>]]

This command is used on the specified window, to set:
- the expected power level value of the measurement.
- the resolution of the window.
- the channel on which the measurement is to be made.

Syntax

```
CONF ➔ 1 ➔ .SCAL ➔ .POW ➔ .AC
               ➔ Space ➔ expected_value ➔ resolution ➔ source list
                   ➔ DEF    ➔ DEF
```

<tr>
<td></td>
<td></td>
<td>(Φ 2) (HP EPM-442A only)</td>
</tr>
</tbody>
</table>

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

CONF1:POW:AC DEF,2,(Φ1)

This command configures the upper window to measure the power of channel A, using the current sensor range and a resolution setting of 2.
MEASurement Instructions

CONFigure[12][:SCALar][:POWer:AC]:RELative [<expected_value>[,<resolution>[,<source list>]]]

This command is used to set the measurement function, range and resolution of the specified window. It sets the measurement function to single channel with relative mode on. The relative value used is that set by the CALCulate:RELative:MAGNitude:AUTO command.

Syntax

```
CONF → 1 → .SCAL → .POW → :AC → .REL
```

Parameters

Refer to “The Optional Parameters”, on page 2-3 for additional details on the parameters in this command.

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.
2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

CONF1:RAT:REL DEF,1,(@1),(@2)

This command configures the upper window to make a ratio measurement of channel A over channel B with relative mode on, using the current sensor range and a resolution setting of 1 on both channels.
FETCh[1/2] Queries

The FETCh? queries set the specified window’s measurement function to either single channel, difference or ratio measurements with relative mode either off or on. They then recalculate the measurement and place the result on the bus. The format of the return is <NR3>, for example, -6.98970004E-001.

The query returns a measurement result whenever it is valid. The measurement result becomes invalid under the following conditions:

- When *RST is executed.
- Whenever a measurement is initiated.
- When any SENSE parameter, such as frequency, is changed.

If data is invalid, the FETCh? query is not completed until all data is valid. The exceptions to this are, if the power meter is in the idle state and the data is invalid, or the power meter has been reconfigured as defined above and no new measurement has been initiated. In such cases, the FETCh? routine generates the error -280, “Data corrupt or stale” and no result is returned. A common cause for this error is receiving a FETCh? after a *RST. If the expected value and resolution parameters are not the same as those that were used to collect the data, error -221, “Settings conflict” occurs.
MEASurement Instructions
FETCh[1|2][:SCALar][:POWer:AC]? [<expected_value>[,<resolution>[,<source_list>]]]

FETCh[1|2][:SCALar][:POWer:AC]? [<expected_value>[,<resolution>[,<source_list>]]]

This command sets the specified window's measurement function to single channel with relative mode off, recalculates the measurement and places the result on the bus. The result is a power based measurement and is expressed in the units defined by UNIT[1|2]:POWer.

Syntax

Parameters

Refer to “The Optional Parameters”, on page 2-3 for additional details on the parameters in this command.

<table>

</tbody>
</table>

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.
2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

FETC2:RAT? DEF,1,(Ω1),(Ω2)  This command queries the lower window’s ratio measurement of channel A over channel B, using the current sensor range and a resolution of 1 on both channels.

Error Messages

If the last measurement on either channel is not valid error -230, “Data corrupt or stale” occurs. A measurement is valid after it has been initiated. It becomes invalid when either a reset occurs or any measurement parameter, for example frequency, is changed.

If the resolution parameter is not the same as the current resolution setting on the specified window, error -221, “Settings conflict” occurs.
FETCh[1|2][:SCALar][:POWer:AC]:RATio:RELative? [<expected_value>[,<resolution>[,<source list>]]]

This command is only relevant for the HP EPM-442A power meter.

This command sets the specified window's measurement function to power ratio with relative mode on, recalculates the measurement and places the results on the bus. The result is a ratio based measurement and is expressed in the units defined by UNIT[1|2]:POWer:RATio. The relative value used is that set by the CALCulate:RELative:MAGNitude:AUTO command.

**Syntax**

```
FETC 1 2
 .SCAL
 .POW :AC :RAT :REL 2
```

**Parameters**

Refer to “The Optional Parameters”, on page 2-3 for additional details on the parameters in this command.

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

FETCh:RAT:REL?

This command queries the relative ratio measurement on the upper window.

Error Messages

If the last measurement on either channel is not valid error -230, “Data corrupt or stale” occurs. A measurement is valid after it has been initiated. It becomes invalid when either a reset occurs or any measurement parameter, for example frequency, is changed.

If the resolution parameter is not the same as the current resolution setting on the specified window, error -221, “Settings conflict” occurs.
READ[1/2] Commands

The READ? commands are most commonly used with the CONFIGure command to cause a new power measurement to be taken and the result returned to the output buffer. The format of the return is <NR3>, for example, -6.98970004E-001.

- For the HP EPM-441A the READ? query is equivalent to:
  ABORT
  INITiate
  FETCH?

- For the HP EPM-442A carrying out a single channel measurement the READ? queries are equivalent to:
  ABORT1
  INITiate1
  FETCH1?
  or
  ABORT2
  INITiate2
  FETCH2?

- For the HP EPM-442A carrying out a difference measurement the READ:DIFference? queries are equivalent to:
  ABORT1and
  ABORT2
  INITiate1
  INITiate2
  FETCH:DIFference?

- For the HP EPM-442A carrying out a ratio measurement the READ:RATio? queries are equivalent to:
  ABORT1
  ABORT2
  INITiate1
  INITiate2
  FETCH:RATio?
MEASurement Instructions

READ[1|2][:SCAlar][:POWerAC]? [<expected_value>,<resolution>,<source list>]}

READ[1|2][:SCAlar][:POWerAC]? [<expected_value>,<resolution>,<source list>]

This command sets the specified window's measurement function to single channel with relative mode off, aborts then initiates the specified channel, calculates the measurement result and places the result on the bus. The result is a power based measurement and is expressed in the units defined by UNIT[1|2]:POWer.

Note

INITiate:CONTInuous must be set to OFF, otherwise error -213, “INIT ignored” occurs. If TRIGGER:SOURCE is set to BUS, error -214, “Trigger deadlock” occurs.

Syntax

Refer to “The Optional Parameters”, on page 2-3 for additional details on the parameters in this command.

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

### Example

```
READ2:RAT? DEF, 1, (@1), (@2)
```

This command queries the lower window's ratio measurement of channel A over channel B, using the current sensor range and a resolution of 1 on both channels.

### Error Messages

**INITiate:CONTInuous** must be set to OFF on both channels, otherwise error -213, “INIT ignored” occurs.

If **TRIGGER:SOURCE** is set to BUS or HOLD on either channel, error -214, “Trigger deadlock” occurs.

If the resolution parameter is not the same as the current resolution setting on the specified window, error -221, “Settings conflict” occurs.
READ[1|2][:SCALar][:POWer:AC]:RATio:RELative? [<expected_value>,<resolution>,<source list>]

This command is only relevant for the HP EPM-442A power meter.

This command sets the specified window's measurement function to ratio mode with relative mode on, aborts then initiates both channel A and B, calculates the ratio measurement result using the new sensor data and places the result on the bus. The result is a ratio based measurement and is expressed in the units defined by \texttt{UNIT[1|2]:POWer:RATio}. The relative value used is that set by the \texttt{CALCulate:RELative:MAGNitude:AUTO} command.

Note \texttt{INITiate:CONTinuous} must be set to \texttt{OFF} on both channels, otherwise error -213, "INIT ignored" occurs. If \texttt{TRIGger:SOURCE} is set to \texttt{BUS} on either channel, error -214, "Trigger deadlock" occurs.

Syntax

Refer to “The Optional Parameters”, on page 2-3 for additional details on the parameters in this command.

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

**Example**

```
READ: RAT: REL?
```

*This command queries the relative ratio measurement on the upper window.*

**Error Messages**

INITiate:CONTinuous must be set to OFF on both channels, otherwise error -213, “INIT ignored” occurs.

If TRIGger:SOURCE is set to BUS or HOLD on either channel, error -214, “Trigger deadlock” occurs.

If the resolution parameter is not the same as the current resolution setting on the specified window, error -221, “Settings conflict” occurs.
MEASure[1/2] Commands

The MEASure? commands configure the power meter to perform a power measurement with the given measurement function, relative mode setting, range and resolution then makes the measurement. The format of the return is <NR3>, for example, -6.98970004E-001. MEASure? is a compound command which is equivalent to:

- For the HP EPM-441A the MEASure? query is equivalent to:
  ABORt
  CONFIGure
  READ?

- For the HP EPM-442A carrying out a single channel measurement the MEASure? queries are equivalent to:
  ABORt1
  CONFIGure
  READ1?

  or
  ABORt2
  CONFIGure
  READ2?

- For the HP EPM-442A carrying out a difference measurement the READ:DIFFerence? queries are equivalent to:
  ABORt1
  ABORt2
  CONFIGure:DIFFerence
  READ:DIFFerence?

- For the HP EPM-442A carrying out a ratio measurement the READ:RATio? queries are equivalent to:
  ABORt1
  ABORt2
  CONFIGure:RATio
  READ:RATio?
MEASurement Instructions
MEASure[1|2][:SCALar][:POWer:AC]? [<expected_value>,<resolution>,<source list>]]

MEASure[1|2][:SCALar][:POWer:AC]? [<expected_value>,<resolution>,<source list>]]

This command sets the specified window's measurement function to single channel with relative mode off, aborts, configures the window then initiates channel A or B, calculates the measurement result and places the result on the bus.

Syntax

Parameters

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

MEAS2:POW:AC? -70DBM, 1, (@1)  
*This command queries the lower window's measurement of channel A, using an expected power level of -70 dBm and a resolution setting of 1.*
MEASurement Instructions

MEASure[1|2][::SCALar][::POWer:AC]:RELative? [<expected_value>,<resolution>,<source_list>]]

This command sets the specified window's measurement function to single channel with relative mode on, aborts, configures then initiates the specified channel, calculates the measurement result and places the result on the bus. The result is a ratio based measurement and is expressed in the units defined by UNIT[1|2]:POWer:RATio. The relative value used is that set by the CALCulate:RELative:MAGNitude:AUTO command.

Syntax

Parameters

Refer to "The Optional Parameters", on page 2-3 for additional details on the parameters in this command.

**Example**

MEAS1:REL? -50DBM,2,(2)

*This command queries the upper window's relative measurement of channel B, using an expected power level of -50 dBm and a resolution setting of 2.*
MEASurement Instructions

**MEASure[1|2]:SCALar]:POWer:AC]:DIFFerence? [<expected_value>[,.<resolution>[,.<source list>]]**

This command is only relevant for the HP EPM-442A power meter.

This command sets the specified window's measurement function to difference mode with relative mode off, aborts, configures then initiates both channel A and B, calculates the difference measurement result and places the result on the bus. The result is a power based measurement and is expressed in the units defined by UNIT[1|2]:POWer.

**Syntax**

```
MEAS 1 :SCAL :POW :AC :DIFF ?

Space <expected_value> DEF

<resolution> DEF

<source list>
```

**Parameters**

Refer to "The Optional Parameters", on page 2-3 for additional details on the parameters in this command.

1. The mnemonic DEF means DEFault. This is not equivalent to the DEFault parameter used in the command sub-systems. The parameters must be entered in the specified order. If parameters are omitted, they will default from the right. The parameter DEFault is used as a place holder. Specifying DEF leaves the parameter value unchanged.

2. When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 to 4 represents a resolution of 1, 0.1, 0.01 and 0.001 respectively.

Example

MEAS : RAT : REL?

This command queries the relative ratio measurement on the upper window.
MEASurement Instructions
MEASure[12]:SCALar[:POWer:AC]:RATio:RELative? [<expected_value>],[<resolution>],[<source list>]]
CALCulate Subsystem
The CALCulate subsystem exists to perform post acquisition data processing. Functions in the SENSE subsystem are related to data acquisition, while the CALCulate subsystem operates on the data acquired by a SENSE function.

The numeric suffix of the CALCulate program mnemonic in the CALCulate commands refers to a window, that is CALCulate1 and CALCulate2 represent the upper and lower windows respectively.

In the power meter there are two independent CALCulate blocks, one for each window. Data from both SENSE blocks may feed either or both CALCulate blocks via the MATH command. Figure 3-1 details where the commands are applied within the CALCulate block.

**Figure 3-1: CALCulate Block**

Input from SENSE1 Block

Input from SENSE2 Block (HP EPM-442A only)
The CALCulate[1|2]:GAIN Node

This node is used to enter and enable a display offset on the specified window. The display offset is applied to the measurement signal after any math calculation.

The commands associated with this block are:

CALCulate[1|2]:GAIN[:MAGNitude] <numeric value>
CALCulate[1|2]:GAIN:STATe <Boolean>
CALCulate Subsystem

CALCulate[1][2]:GAIN[:MAGNitude] <numeric_value>

This command is used to enter a value for the display offset on the specified window. The display offset is applied to the measurement signal after any math calculation.

Entering a value using this command automatically turns the CALCulate[1][2]:GAIN:STATE command to ON.

Syntax

```
CALC 1 .GAIN .MAGN Space numeric_value
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value. The default value, DEF, is 0 dB. The value for MIN is -100.000 dB. The value for MAX is +100.000 dB.</td>
<td>-100.000 to +100.000 dB</td>
</tr>
</tbody>
</table>

Example

```
CALC2:GAIN 20
```

*This command enters a display offset of 20 dB to the lower window.*

Reset Condition

On reset, the display offset is set to 0 dB (DEF).
CALCulate Subsystem

CALCulate[1|2]:GAIN[:MAGNitude] <numeric_value>

Query

CALCulate[1|2]:GAIN[:MAGNitude]? [MIN|MAX]

The query returns the current setting of the display offset or the value associated with MIN and MAX.

Query Example

CALC1:GAIN?

This command queries the current setting of the display offset on the upper window.

Error Message

If CALCulate[1|2]:GAIN[:MAGNitude] is set to ON while SENSE:SPEED is set to 200, the error -221, "Settings Conflict" occurs.
CALCulate Subsystem
CALCulate[1|2]:GAIN:STATe <Boolean>

CALCulate[1|2]:GAIN:STATe <Boolean>

This command is used on the specified window to enable and disable the display offset set by the CALCulate[1|2]:GAIN[:MAGnitude] command.

Syntax

![Diagram of syntax]

Example

CALC2:GAIN:STAT 1

*This command enables the display offset set for the lower window.*

Reset Condition

On reset, the gain is disabled.

Query

CALCulate[1|2]:GAIN:STATe?

The query enters a 1 or 0 into the output buffer indicating the status of the display offset.

- 1 is returned when the display offset feature is enabled.
- 0 is returned when the display offset feature is disabled.

Query Example

CALC1:GAIN:STAT?

*This command queries whether the display offset on the upper window is on or off.*

Error Message

If CALCulate[1|2]:GAIN:STATe is set to ON while SENSE:SPeed is set to 200, the error -221, “Settings Conflict” occurs.
The CALCulate[1|2]:MATH Node

This node is a generic SCPI calculate sub-block which can be specified to define and carry out mathematical transformation on SENSE data. In the power meter a windows math block is used to set whether the window is measuring in single channel, difference or ratio modes.

The commands associated with this node are:

CALCulate[1|2]:MATH[:EXPRession]
CALCulate[1|2]:MATH[:EXPRession]:CATalog?
CALCulate Subsystem
CALCulate[1|2]:MATH[:EXPRESSION] <string>

This command is used to set the specified window to a single channel, difference or ratio measurement.

Syntax

```
CALC  1   MATH     EXPR     Space  string
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
</table>
| string  | A single string value detailing the measurement type. For the HP EPM-441A the default is SENS1. For the HP EPM-442A the default is SENS1 if the upper window is selected or SENS2 if the lower window is selected. | *(SENS1)*
|         |                                                                                     | *(SENS2)*                               |
|         |                                                                                     | *(SENS1-SENS2)*                         |
|         |                                                                                     | *(SENS2-SENS1)*                         |
|         |                                                                                     | *(SENS1/SENS2)*                         |
|         |                                                                                     | *(SENS2/SENS1)*                         |

1. Either single or double quotes may be used. However, quotes are mandatory.
2. HP EPM-442A only.

Example

```
CALC2:MATH "(SENS2/SENS1)"
```

*This command sets the lower window to make a channel B/A ratio measurement.*

Reset Condition

On reset, the HP EPM-441A upper and lower windows are both set to channel A (*SENS1*). On the HP EPM-442A the upper window is set to channel A (*SENS1*) and the lower window to channel B (*SENS2*).
CALCulate Subsystem
CALCulate[1|2]:MATH[:EXPRession] <string>

Query

CALCulate[1|2]:MATH[:EXPRession]?  
The query returns the current math measurement setting on the specified window.

Query Example

CALC1:MATH?  
This command queries the current setting of the math expression on the upper window.

Error Messages

For the HP EPM-442A, if CALCulate1:MATH is set to anything other than SENS1 while SENSE:SPEED is set to 200, the error -221, “Settings Conflict” occurs.

For the HP EPM-442A, if CALCulate2:MATH is set to anything other than SENS2 while SENSE:SPEED is set to 200, the error -221, “Settings Conflict” occurs.
CALCulate Subsystem
CALCulate[1|2]:MATH[:EXPRession]:CATalog?

This query lists all the defined expressions. The response is a list of comma separated strings. Each string contains an expression.

For the HP EPM-441A the string is:
"(SENS1)"

For the HP EPM-442A the string is:
"(SENS1)^,(SENS2)^,(SENS1/SENS2)^,
(SENS2/SENS1)^,(SENS1-SENS2)^,(SENS2-SENS1)^"

Syntax

Example

CALC1:MATH:CAT?

This command lists all the defined math expressions.
The CALCulate[1|2]:RELative Node

This node contains commands which allow you to compare the measurement signal to a reference value.

Within the CALCulate block the relative value is applied to the measurement signal after any math calculations and display offsets have been applied.

The commands associated with this node are:

CALCulate[1|2]:RELative[:MAGnitude]:AUTO <Boolean>|ONCE
CALCulate[1|2]:RELative:STATe <Boolean>
CALCulate Subsystem

CALCulate[1|2]:RELative[:MAGNitude]:AUTO <Boolean>:ONCE

This command is used to set the reference value to be used in the relative measurement. Within the CALCulate block the relative value is applied to the measurement signal after any math calculations and display offsets have been applied.

This command should be set to ONCE to set the reference value to be used in relative measurements. Selecting ONCE sets the reference value to being that of the measurement signal after any math calculations and display offsets have been applied. After the reference value has been set the command returns to OFF. Setting this command to ONCE turns the CALCulate[1|2]:RELative:STATE command to ON.

If OFF is selected, no reference value is applied to the measurement signal. There is no situation in which you would want to send this command with OFF. OFF is only available because it is required for the query response.

If ON is selected, it causes the error -224, “Illegal parameter value” to occur.

Syntax

Example

CALC1:REL:AUTO ONCE

This command sets a reference value to be used in the relative measurement on the upper window.
CALCulate Subsystem

CALCulate[1|2]:RELative[:MAGNitude]:AUTO <Boolean>::ONCE

Query

CALCulate[1|2]:RELative[:MAGNitude]:AUTO?

The query always returns OFF.

Error Message

If CALCulate:RELative[:MAGNitude]:AUTO is set to ONCE while SENSE:SPEED is set to 200, the error -221, "Settings Conflict" occurs.

If this command is set to ON the error -224, "Illegal parameter value" occurs.
CALCulate Subsystem
CALCulate[1|2]:RELative:STATe <Boolean>

CALCulate[1|2]:RELative:STATe <Boolean>
This command is used to enable and disable relative mode. If the command is:
- disabled, the measurement signal remains unchanged.
- enabled, the current relative value set by CALCulate:RELative:MAGnitude:AUTO is applied to the measurement signal.

Syntax

![Diagram of syntax](image)

Example

calc1:rel:stat off

This command disables the relative mode on the upper window.

Reset Condition
On reset, relative mode is disabled.

Query

CALCulate[1|2]:RELative:STATe?
The query returns a 1 or 0 into the output buffer.
- 1 is returned when relative mode is enabled.
- 0 is returned when relative mode is disabled.

Query Example

calc1:rel:stat?

This command queries whether relative mode is off or on.

Error Message
If CALCulate:RELative:STATe is set to ON while SENSE:SPEed is set to 200, the error -221, "Settings Conflict" occurs.
CALibration Subsystem
CALibration Subsystem

The CALibration command subsystem is used to zero and calibrate the power meter. It is also used to set the reference calibration factor for the power sensor which is being used.

The numeric suffix of the CALibration program mnemonic in the CALibration commands refers to a channel, that is CALibration1 and CALibration2 represent channel A and channel B respectively. If you are using the single channel HP EPM-441A power meter the CALibration2 commands are irrelevant and cause the error “Header suffix out of range.”

Zeroing and calibration of the power meter is recommended:

- when a 5°C change in temperature occurs.
- when you change the power sensor.
- every 24 hours.
- prior to measuring low level signals. For example, 10 dB above the lowest specified power for your sensor.

The CALibration commands, with the exception of RCPFactor, are all overlapped commands, that is, the power meter can continue parsing and executing subsequent commands while initiated. Refer to “Using the Operation Complete Commands”, on page 1-78 to determine when the commands are complete.

4-2 HP EPM-441A/442A Programming Guide
This command causes the power meter to perform a calibration sequence on the specified channel. The command assumes that the power sensor is connected to the POWER REF output. The calibration sequence consists of:

- Zeroing the power meter (CALibration:ZERO:AUTO ONCE), and
- calibrating the power meter (CALibration:AUTO ONCE).

For the HP 8480 series power sensors the reference calibration factor used during this calibration can be derived from either an active sensor calibration table or the value entered using CALibration:RCFactor. The actual value used is the one which was most recently set. That is, a value entered using CALibration:RCFactor is overridden if a sensor calibration table is subsequently selected and enabled. Conversely, CALibration:RCFactor overrides any reference calibration factor previously set from a sensor calibration table. To determine the currently set reference calibration factor use CALibration:RCFactor?

The HP E-series power sensors have their sensor calibration tables stored in EEPROM which means that the reference calibration factor is automatically downloaded by the power meter.

**Syntax**

```
CAL1:ALL
```

**Example**

```
CAL1:ALL
```

*This command causes the power meter to perform a calibration sequence on channel A.*
Error Message

If the calibration was not carried out successfully the error -231, “Data Questionable; CAL ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.

If zeroing was not carried out successfully the error -231, “Data Questionable; ZERO ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.
This query is identical to CALibration[1|2][:ALL], however, unlike the command, this query provides a response to indicate whether the calibration has been successful or not.

This query causes the power meter to perform a calibration sequence on the specified channel. The query assumes that the power sensor is connected to the POWER REF output. The calibration sequence consists of:

- Zeroing the power meter (CALibration:ZERO:AUTO ONCE), and
- Calibrating the power meter (CALibration:AUTO ONCE).

When the calibration sequence is completed, 0 or 1 is entered into the output buffer to indicate if the sequence was successful. If the result is:

- 0, the calibration has passed.
- 1, the calibration has failed.

For the HP 8480 series power sensors the reference calibration factor used during this calibration can be derived from either an active sensor calibration table or the value entered using CALibration:RCFactor. The actual value used is the one which was most recently set. That is, a value entered using CALibration:RCFactor is overridden if a sensor calibration table is subsequently selected and enabled. Conversely, CALibration:RCFactor overrides any reference calibration factor previously set from a sensor calibration table. To determine the currently set reference calibration factor use CALibration:RCFactor?

The HP E-series power sensors have their sensor calibration tables stored in EEPROM which means that the reference calibration factor is automatically downloaded by the power meter.
Query Example

```
CAL1 : ALL?
```

This command causes the power meter to perform a calibration sequence on channel A and return a result.

Error Message

If the calibration was not carried out successfully the error -231, “Data Questionable; CAL ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.

If zeroing was not carried out successfully the error -231, “Data Questionable; ZERO ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.
CALibration[1|2]:AUTO <Boolean> ONCE

This command is used to calibrate the specified channel when ONCE is selected. The command assumes that the power sensor is connected to a 1 mW reference signal. The 0|OFF parameter is only required for the query response and is ignored in the command. If 1|ON is selected, it causes the error -224, “Illegal parameter value” to occur.

For the HP 8480 series power sensors the reference calibration factor used during this calibration can be derived from either an active sensor calibration table or the value entered using CALibration:RCFactor. The actual value used is the one which was most recently set. That is, a value entered using CALibration:RCFactor is overridden if a sensor calibration table is subsequently selected and enabled. Conversely, CALibration:RCFactor overrides any reference calibration factor previously set from a sensor calibration table. To determine the currently set reference calibration factor use CALibration:RCFactor?

The HP E-series power sensors have their sensor calibration tables stored in EEPROM which means that the reference calibration factor is automatically downloaded by the power meter.

**Note**

The power meter should be zeroed before calibration using the CALibration:ZERO:AUTO ONCE command.

**Syntax**

```
CAL 1 AUTO Space 0|OFF ONCE
```

**Example**

```
CAL1:AUTO ONCE
```

This command causes the power meter to perform a calibration on channel A.

**Reset Condition**

On reset, automatic calibration is disabled.
CALibration Subsystem
CALibration[1|2]:AUTO <Boolean>IONCE

Query
CALibration[1|2]:AUTO?
The query always returns a value of 0.

Error Message
If the calibration was not carried out successfully the error -231, “Data Questionable; CAL ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.

If this command is set to ON the error -224, “Illegal parameter value” occurs.
CALibration[1/2]:RCFactor <numeric_value>

This command is used with HP 8480 series power sensors to set the reference calibration factor of the specified channel. Reference calibration factors can also be set using sensor calibration tables. The power meter uses the most recently set reference calibration factor.

Syntax

```
CAL \rightarrow 1 \rightarrow \text{RCF} \rightarrow \text{Space} \rightarrow \text{numeric_value}
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value. The default value, DEF, is 100%. The value for MIN is 1%. The value for MAX is 150%.</td>
<td>1.0 to 150.0FCT DEF MIN MAX</td>
</tr>
</tbody>
</table>

Example

```
CAL1:RCF 98
```

This command enters a reference calibration factor of 98% to channel A.

Reset Condition

On reset, the reference calibration factor is set to 100%.
CALibration Subsystem

CALibration[1|2]:RCFactor <numeric_value>

Query

CALibration[1|2]:RCFactor? [MIN|MAX]

The query returns the current setting of the reference calibration factor or the values associated with MIN and MAX.

Query Example

CAL2:RCF?

This command queries the reference calibration factor of channel B.

Error Message

If this command is used when an HP E-series power sensor is connected the error -241, “Hardware missing” occurs.
CALibration[1/2]:ZERO:AUTO <Boolean>IONCE

This command causes the power meter to perform its zeroing routine on the specified channel when ONCE is selected. Zeroing takes approximately 10 seconds. This adjusts the power meter for a zero power reading with no power supplied to the power sensor. The OFF parameter is only required for the query response and is ignored in the command. If ON is selected, it causes the error -224, “Illegal parameter value” to occur.

The command assumes that the power sensor is not connected to a power source.

Syntax

```
CAL  
   ↓  
   1  
   ZERO  
   AUTO  
   Space  
   0 | OFF  
   ONCE  
   ?
```

Example

```
CAL2:ZERO:AUTO ONCE
```

This command causes the power meter to perform a zeroing routine on channel B.

Reset Condition

On reset, automatic zeroing is disabled.

Query

```
CALibration[1/2]:ZERO:AUTO?
```

The query always returns a value of 0.

Error Message

If zeroing was not carried out successfully the error -231, “Data Questionable; ZERO ERROR” occurs. If you are using the HP EPM-442A the error message specifies on which channel the calibration failed.

If this command is set to ON the error -224, “Illegal parameter value” occurs.
CALibration Subsystem
CALibration[12]: ZERO: AUTO <Boolean>: ONCE
DISPlay Subsystem
The DISPLAY subsystem is used to control the selection and presentation of the windows used on the power meter's display.

**DISPlay:CONTrast <numeric_value>**

This command is used to control the display contrast. A contrast of:

- 0, represents a minimum contrast.
- 1, represents a maximum contrast.

When the supply power is cycled off then on the contrast sets to the factory default for that particular power meter.

**Syntax**

![Syntax Diagram]

**Parameters**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the contrast level. The default, DEF, is the factory default and can vary between power meters. The value for MIN is 0. The value for MAX is 1.</td>
<td>0 to 1</td>
</tr>
</tbody>
</table>

**Example**

```
DISP:CONT 0.75
```

*This command sets the display contrast to 0.75.*

**Reset Condition**

On reset, the contrast is not affected.
DISPlay Subsystem
DISPlay:CONTrast <numeric_value>

Query

DISPlay:CONTrast? [MIN|MAX]

The query returns the current setting of the contrast or the values associated with MIN and MAX. The response format is <NR3>.

Query Example

DISP:CONT?

This command queries the current contrast setting.
**DISPlay:ENABle <Boolean>**

This command is used to enable and disable the display. At power-up the display is always enabled.

**Syntax**

```
DISP → ENAB → Space → OFF
```

**Example**

```
DISP:ENAB 0
```

*This command disables the display.*

**Reset Condition**

On reset, the display is enabled.

**Query**

```
DISPlay:ENABLE?
```

The query returns a 1 or 0 into the output buffer.

- 1 is returned when the display is enabled.
- 0 is returned when the display is disabled.

**Query Example**

```
DISP:ENAB?
```

*This command queries whether the display is on or off.*
Display Subsystem
Display[::WINDow[12]] Node

Display[::WINDow[12]] Node

This node is used to control various characteristics of the display windows.

The numeric suffix of the WINDow program mnemonic in the Display commands refers to a window, that is WINDow1 and WINDow2 represent the upper and lower windows respectively.

The commands associated with this node are:

DISPLAY[::WINDow[12]]::FORMat <character_data>
DISPLAY[::WINDow[12]]::METER:LOWer <numeric_value>
DISPLAY[::WINDow[12]]::METER:UPPer <numeric_value>
DISPLAY[::WINDow[12]]::RESolution <numeric_value>
DISPLAY[::WINDow[12]]::SELECT
DISPLAY[::WINDow[12]]::STATE <Boolean>
**DISPLAY Subsystem**

**DISPLAY[:WINDow[1|2]]::FORMat <character_data>**

This command is used to select the format, either analog or digital, of the selected window.

**Syntax**

```
    DISP :WIND 1 :FORM Space character_data DEF ?
```

**Parameters**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_data</td>
<td>Character data for the window format. For the HP EPM-441A the default for the upper window is DIGital and ANALog for the lower window. For the HP EPM-442A the defaults for the upper and lower windows are DIGital.</td>
<td>DIGital ANALog DEF</td>
</tr>
</tbody>
</table>

**Example**

```
    DISP;WIND2::FORM DIG
```

*This command sets the lower window to a digital display.*

**Reset Condition**

On reset, the HP EPM-441A upper window is DIGital and the lower window ANALog. For the HP EPM-442A the defaults for the upper and lower windows are DIGital.

**Query**

```
    DISPlay:[WINDow[1|2]]::FORMat?
```

The query returns the current format of the selected window, either ANAL or DIG.
DISPlay Subsystem
DISPlay[:WINDow[1|2]]:FORMat <character_data>

Query Example

DISP:FORM?

This command queries the current format of the upper window.
DISPlay[:WINDe[1|2]]:METer Node

This command node is used to control the upper and lower limits of the analog meter.

The commands associated with this node are:

DISPlay[:WINDe[1|2]]:METer:LOWer <numeric_value>
DISPlay[:WINDe[1|2]]:METer:UPPer <numeric_value>
DISPlay Subsystem

DISPlay[:WINDow[1|2]]:METer:LOWer <numeric_value>

This command is used to set the analog meter lower limit. The units used are dependent on the current setting of UNIT:POWer and CALCulate:RELative:STATe as shown in Table 5-1.

### Table 5-1: Measurement Units

<table>
<thead>
<tr>
<th>Measurement Mode</th>
<th>CALC:REL:STAT OFF</th>
<th>CALC:REL:STAT ON</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Linear</td>
<td>Log</td>
</tr>
<tr>
<td>Single Channel</td>
<td>Watt</td>
<td>dBm</td>
</tr>
<tr>
<td>Ratio</td>
<td>%</td>
<td>dB</td>
</tr>
<tr>
<td>Difference</td>
<td>Watt</td>
<td>dBm</td>
</tr>
</tbody>
</table>

### Syntax

DISP .WIND 1 .MET .LOW Space numeric_value

### Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the analog meter lower limit. The default, DEF, is -70 dBm. The value for MIN is -150 dBm. The value for MAX is 230 dBm. The default units are defined by UNIT:POWer and CALCulate:RELative:STATe.</td>
<td>-150 to 230 dBm</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DEF</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MAX</td>
</tr>
</tbody>
</table>
Example

```
DISP:WIND2:MET:LOW 10
```

This command sets the lower window's analog meter lower limit.

Reset Condition

On reset, the lower limit is set to -70 dBm (DEF).

Query

```
DISPlay[:WINDow[1|2]]:METer:LOWer? [MIN|MAX]
```

The query returns the current setting of the analog meter's lower limit or the value associated with MIN and MAX. The format of the response is `<NR3>`. The units in which the results are returned is dependent on the current setting of UNIT POWER and CALCulate:RELative:STATe as shown in Table 5-1.

Query Example

```
DISP:MET:LOW?
```

This command queries the lower limit set on the analog meter in the upper window.
**Display Subsystem**

**Display[:Window[1|2]]::Meter:Upper <numeric_value>**

This command is used to set the analog meter upper limit. The units used are dependent on the current setting of **Unit:Power** and **Calculate:Relative:State** as shown in Table 5-1.

### Table 5-2: Measurement Units

<table>
<thead>
<tr>
<th>Measurement Mode</th>
<th>CALC:REL:STAT OFF</th>
<th>CALC:REL:STAT ON</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Single Channel</td>
<td>Watt</td>
<td>dBm</td>
</tr>
<tr>
<td>Ratio</td>
<td>%</td>
<td>dB</td>
</tr>
<tr>
<td>Difference</td>
<td>Watt</td>
<td>dBm</td>
</tr>
</tbody>
</table>

**Syntax**

```
$DISP$ :WIND 1 :MET :UPP numeric_value
```

**Parameters**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the analog meter upper limit. The default, DEF, is 20 dBm. The value for MIN is -150 dBm. The value for MAX is 230 dBm. The default units are defined by <strong>Unit:Power</strong>. The default units are defined by <strong>Unit:Power</strong> and <strong>Calculate:Relative:State</strong>.</td>
<td>-150 to 230 dBm</td>
</tr>
</tbody>
</table>
Example

```plaintext
DISP:WIND2:MET:UPP 20
```

This command sets the lower window's analog meter upper limit.

Reset Condition

On reset, the upper limit is set to 20 dBm (DEF).

Query

```plaintext
DISPlay[:WINDow[1|2]]:METer:UPPer? [MIN|MAX]
```

The query returns the current setting of the analog meter's upper limit or the value associated with MIN and MAX. The format of the response is <NR3>. The units in which the results are returned is dependent on the current setting of UNIT:POWER and CALCulate:RELative:STATe as shown in Table 5-1.

Query Example

```plaintext
DISP:WIND2:MET:UPP?
```

This command queries the upper limit set on the analog meter in the lower window.
DISPlay Subsystem

DISPlay[:WINDow[12]]:RESolution <numeric_value>

This command is used to set the resolution of the measurement result in the selected window.

When the measurement result is linear this parameter represents the number of significant digits. When the measurement result is logarithmic 1 through 4 represents a resolution of 1, 0.1, 0.01, and 0.001 respectively.

The resolution set for the measurement window also affects the level of averaging in the SENSE subsystem when auto averaging is selected. Also, as a measurement from a selected channel may be displayed in more than one window (either directly as a single channel measurement or with a ratio or difference measurement (HP EPM-442A only)) there is a defined relationship between the window resolution and the resolution used to determine the auto averaging level. The resolution level used to determine auto averaging for a selected channel is the greater of the resolutions set for all windows in which the channel is displayed.

Syntax

![Syntax Diagram]

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the window resolution. DEF is 3, MIN is 1, and MAX is 4.</td>
<td>1, 2, 3, 4, DEF, MIN, MAX</td>
</tr>
</tbody>
</table>
DISPLAY Subsystem

DISPLAY[:WINdow[1|2]]:RESolution <numeric_value>

Example

DISP:WINd2:RES 4

This command sets the lower window's resolution to 4 significant digits if the measurement result is linear or 0.001 if the measurement result is logarithmic.

Reset Condition

On reset, the resolution is set to 3 (DEF).

Query

DISPLAY[:WINdow[1|2]]:RESolution? [MIN|MAX]

The query returns the current setting of the window’s resolution or the value associated with MIN and MAX. The format of the response is <NR1>.

Query Example

DISP:RES?

This command queries the resolution setting of the upper window.
**DISPlay Subsystem**

**DISPlay[:WINDow[1|2]]::SELect**

This command is used to determine which window is currently selected.

**Syntax**

![Diagram of DISPlay][:WINDow[1|2]]::SELect]

**Example**

DISP::WIND2::SEL

*This command selects the lower window.*

**Reset Condition**

On reset, the upper window is selected.

**Query**

DISPlay[:WINDow[1|2]]::SELect?

The query enters a 1 or 0 into the output buffer indicating whether the window specified is currently selected.

- 1 is returned if the specified window is selected.
- 0 is returned if the specified window is not selected.

**Query Example**

DISP::SEL?

*This command queries whether or not the upper window is selected.*
**Display Subsystem**

**Display[:Window[1/2]]::State** <Boolean>

This command is used to enable and disable the selected window, therefore allowing you to toggle between single and dual measurement window's on the display.

Only one window can be disabled at any one time. If you disable the only remaining window then the other window is automatically enabled and becomes the currently active window.

**Syntax**

```
DISP :WIND 1 ::STAT 0 | OFF
```

**Example**

```
DISP:WIND1:STAT 1
DISP:WIND2:STAT 1

This command enables both the upper and lower window giving a dual measurement display.
```

**Reset Condition**

On reset, both windows are enabled.

**Query**

```
Display[:Window[1/2]]::State?
```

The query enters a 1 or 0 into the output buffer indicating the state of the selected window.

- 1 is returned if the window is enabled.
- 0 is returned if the window is disabled.

**Query Example**

```
DISP:WIND2:STAT?

This command queries whether or not the lower window is displayed.
```
DISPLAY Subsystem
DISPLAY[:WINdow[1|2]][:STATe] <Boolean>
FORMat Subsystem
The `FORMat` subsystem sets a data format for transferring numeric information. This data format is used only for response data by those commands that are specifically designated to be affected by the `FORMat` subsystem.

For the HP EPM-442A the same `FORMat` is used on both channels.

The queries that are affected are:

- `FETCH?`
- `READ?`
- `MEASURE?`

When the format type is ASCII, numeric data is output as ASCII bytes in the `<NR3>` format.

When the format type is real, numeric data is output as a definite length block as IEEE 754 64 bit floating point numbers. The result is an 8 byte block per number.

<table>
<thead>
<tr>
<th>Keyword</th>

</tbody>
</table>

6-2 HP EPM-441A/442A Programming Guide
FORMat[:READings]:BORDer NORMAL SWAPped

This command is used to control whether the binary data is transferred in normal or swapped Byte ORDER. It is only used when FORMat[:READings][:DATA] is set to REAL.

Syntax

```
FORM READ BORD [Space] NORM SWAP
```

Example

```
FORM:BORD SWAP
```

This command sets the byte order to swapped.

Reset Condition

On reset, this value is set to NORMAL.

Query

```
FORMat[:READings]:BORDer?
```

The query returns the current setting of the byte order. The format of the response is <character_data>.

Query Example

```
FORM:BORD?
```

This command queries the current byte order setting.
FORMAT Subsystem

FORMAT[:READings][:DATA] <Type>

This command is used to set the data format to either ASCII or REAL.

Syntax

```
FORMAT :READ :DATA Space Type
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Character data (not string).</td>
<td>ASCII, REAL</td>
</tr>
</tbody>
</table>

Example

```
FORM REAL
```

This command sets the format to real.

Reset Condition

On reset, the format is set to ASCII.

Query

```
FORMAT[:READings][:DATA]?
```

The query returns the current setting of format. The format of the response is `<character_data>`.

Query Example

```
FORM?
```

This command queries the current format setting.
FORMat Subsystem
FORMat[:READings][:DATA] <Type>
MEMory Subsystem
MEMory Subsystem

The MEMory command subsystem is used to create, edit and review sensor calibration tables. This facility can be used to store sensor calibration tables for the HP 8480 series power sensors. The sensor calibration tables remain stored in the power meter's memory during power down. The power meter is capable of storing 20 sensor calibration tables of 80 frequency points each.

The power meter automatically downloads the HP E-series power sensors calibration tables. These tables cannot be reviewed or edited.

This subsystem is also used to create and review save/recall registers.

MEMory:CATalog Node

This node is used to query information on the current contents of the power meter’s sensor calibration tables and save/recall registers.

The commands associated with this node are:

MEMory:CATalog[:ALL]?  
MEMory:CATalog:STATE?  
MEMory:CATalog:TABLE?
MEMory Subsystem
MEMory:CATalog[:ALL]?

MEMory:CATalog[:ALL]?

This command is used to list the stored sensor calibration tables and save/recall registers.

The power meter returns the data in the form of two numeric parameters and as many strings as there are stored sensor calibration tables and save/recall registers.

<numERIC_value>,<numERIC_value>({,<string>})

- The first numeric parameter indicates the amount of memory, in bytes, used for the storage of tables and registers.
- The second numeric parameter indicates the memory, in bytes, available for the storage of tables and registers.
- Each string parameter returned indicates the name, type and size of a stored sensor calibration table or save/recall register:
  - <string>,<type>,<size>
  - <string> indicates the name of the sensor calibration table or save/recall register.
  - <type> indicates TABL for a sensor calibration table or STAT for a save/recall register.
  - <size> indicates the size of the sensor calibration table or save/recall register in bytes.

For example, a sample of a response may look like:

1178,26230,"DEFAULT,TABL,14","HP8481A,TABL,116",
"HP8482A,TABL,74",............"State0,STAT,1619",
"State1,STAT,1619","State2,STAT,1619" ............

7.4  HP EPM-441A/442A Programming Guide
The power meter is shipped with a set of predefined sensor calibration tables. The data in these sensor calibration tables is based on statistical averages for a range of Hewlett-Packard power sensors. These tables can be altered. The predefined data is listed in your User's Guide. These power sensors are:

<table>
<thead>
<tr>
<th>Table</th>
<th>Power Sensor</th>
<th>Table Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>None</td>
<td>DEFAULT(^1)</td>
</tr>
<tr>
<td>1</td>
<td>HP 8481A</td>
<td>HP8481A</td>
</tr>
<tr>
<td>2</td>
<td>HP 8482A, HP 8482B, HP 8482H</td>
<td>HP8482A</td>
</tr>
<tr>
<td>3</td>
<td>HP 8483A</td>
<td>HP8483A</td>
</tr>
<tr>
<td>4</td>
<td>HP 8481D</td>
<td>HP8481D</td>
</tr>
<tr>
<td>5</td>
<td>HP 8485A</td>
<td>HP8485A</td>
</tr>
<tr>
<td>6</td>
<td>HP R8486A</td>
<td>R8486A</td>
</tr>
<tr>
<td>7</td>
<td>HP Q8486A</td>
<td>Q8486A</td>
</tr>
<tr>
<td>8</td>
<td>HP R8486D</td>
<td>R8486D</td>
</tr>
<tr>
<td>9</td>
<td>HP 8487A</td>
<td>HP8487A</td>
</tr>
</tbody>
</table>

1. Default is a sensor calibration table in which the reference calibration factor and calibration factors are 100%. This sensor calibration table can be used during the performance testing of the power meter.

There are also ten sensor calibration tables named CUSTOM_0 through CUSTOM_9 which do not contain any data when the power meter is shipped from the factory.

**Syntax**

```
MEM\rightarrow{:CAT}\rightarrow{:ALL}\rightarrow{?}\rightarrow
```

**Example**

```
MEM{:CAT}\?
```

*This command queries the list of stored sensor calibration tables and save/recall registers.*

---

HP EPM-441A/442A Programming Guide 7-5
MEMory Subsystem
MEMory:CATalog:STATe?

MEMory:CATalog:STATe?

This command is used to list the save/recall registers.

The power meter returns the data in the form of two numeric parameters and as many strings as there are save/recall registers.

\(<\text{numeric\_value}>, \text{numeric\_value}\),\(<\text{string}>)\)

- The first numeric parameter indicates the amount of memory, in bytes, used for the storage of registers.
- The second parameter indicates the memory, in bytes, available for the storage of registers.
- Each string parameter returned indicates the name, type and size of a save/recall register:

  - \(<\text{string}>, \text{type}, \text{size}>\)
  - \(<\text{string}>\) indicates the name of the save/recall register.
  - \(<\text{type}>\) indicates \text{STAT} for save/recall register.
  - \(<\text{size}>\) indicates the size of the save/recall register in bytes.

For example, a sample of a response may look like:

0,16190,"State0,STAT,0","State1,STAT,0" ...........

Syntax

MEM\rightarrow\text{:CAT}\rightarrow\text{:STAT}\rightarrow?\rightarrow

Example

MEM:CAT:STAT?

\text{This command queries the list of save/recall registers.}
MEMory:CATalog:TABLE?

This command is used to list the stored sensor calibration tables.

The power meter returns the data in the form of two numeric parameters and as many strings as there are stored sensor calibration tables.

\(<\text{numeric\_value}>,\text{numeric\_value}\rangle,\langle\text{string}\rangle\)

- The first numeric parameter indicates the amount of memory, in bytes, used for the storage of tables.
- The second parameter indicates the memory, in bytes, available for the storage of tables.
- Each string parameter returned indicates the name, type and size of a stored sensor calibration table:
  - \(<\text{string}>,\text{type},\text{size}\>
  - \(<\text{string}\rangle\) indicates the name of the sensor calibration table.
  - \(<\text{type}\rangle\) indicates TABL for a sensor calibration table.
  - \(<\text{size}\rangle\) indicates the size of the sensor calibration table in bytes.

For example, a sample of a response may look like:

1178,10040,"DEFAULT,TABL,14","HP8481A,TABL,116","HP8482A,TABL,74","HP8483A,TABL,62".............
MEMory Subsystem
MEMory:CATalog:TABLE?

1. Default is a sensor calibration table in which the reference calibration factor and calibration factors are 100%. This sensor calibration table can be used during the performance testing of the power meter.

There are also ten sensor calibration tables named CUSTOM_0 through CUSTOM_9 which do not contain any data when the power meter is shipped from the factory.

Syntax

MEM • CAT • TABL • ?

Example

MEM:CAT:TABL? This command queries the list of stored sensor calibration tables.
MEMory Subsystem
MEMory:CLEar Node

MEMory:CLEar Node

This node is used to remove the contents stored in the sensor calibration tables and save/recall registers. This subsystem removes the data contents but does not affect the name of the associated sensor calibration table or save/recall register.

The commands associated with this node are:

MEMory:CLEar: [NAME] <string>
MEMory:CLEar:TAble

Note

The contents cleared using these commands are non-recoverable.
MEMory Subsystem
MEMory:CLEar[:NAME] <string>

MEMory:CLEar[:NAME] <string>

This command is used to clear the contents of a given sensor calibration table or save/recall register.

Although the sensor calibration table remains, a MEMory:TABLE:FREQuency|GAIn:POInts? query returns a 0 as there are no contents in the sensor calibration table.

For sensor calibration tables this command is an alternative form of the MEMory:CLEar:TABLE command, the only difference being the method in which the sensor calibration table is selected.

Note
The contents cleared using this command are non-recoverable.

Syntax

MEMory:CLEar[:NAME] <string>

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>String data.</td>
<td>Any existing sensor calibration table name or save/recall register.</td>
</tr>
</tbody>
</table>

Example

MEM:CLE "HP8485A"  

This command clears the contents of sensor calibration table  
HP 8485A

Error Messages

If the sensor calibration table or save/recall register name does not exist error -224, "Illegal parameter value" occurs.
MEMory:CLEar:TABLE

This command is used to clear the contents of the sensor calibration table, currently selected using MEMory:TABLE:SELECT. Although the sensor calibration table remains, a MEMory:TABLE:FREQuency:GAIN:POINts? query returns a 0 as there are no contents in the sensor calibration table.

For sensor calibration tables, this command is an alternative form of the MEMory:CLEar[:NAME] command, the only difference being the method in which the sensor calibration table is selected.

Note
The contents cleared using this command are non-recoverable.

Syntax

MEM:CLEAR:TABLE

Example

MEM:CLEAR:TABLE
This command clears the contents of the currently selected sensor calibration table.

Error Message

If no sensor calibration table is selected error -221, “Settings conflict” occurs.
MEMory Subsystem
The MEMory:FREE Node

The MEMory:FREE Node

This node is used to return information on the amount of free memory space available for sensor calibration tables and save/recall registers.

The commands associated with this node are:
MEMory:FREE[:ALL]?
MEMory:FREE:STATe?
MEMory:FREE:TABLE?
MEMory:FREE[:ALL]?

This query returns the amount of memory free for both the sensor calibration tables and save/recall registers. The format of the response is:

<bytes_available>,<bytes_in_use>

Syntax

MEM :FREE :ALL ?

Example

MEM:FREE?  This command queries the amount of free memory in total.
MEMory Subsystem
MEMory:FREE:STATe?

MEMory:FREE:STATe?

This query returns the amount of memory free for save/recall registers. The format of the response is:

<bytes_available>,<bytes_in_use>

Syntax

```
MEM:FREE:STAT?
```

Example

```
MEM:FREE:STAT?
```

This command queries the amount of free memory for save/recall registers.
MEMory:FREE:TABLE?

This query returns the amount of memory free for sensor calibration tables. The format of the response is:

<bytes_available>,<bytes_in_use>

Syntax

```
MEM:FREE:TABL?
```

Example

```
MEM:FREE:TABL?  This command queries the amount of free memory for sensor calibration tables.
```
MEMory Subsystem
MEMory:NSTates?

MEMory:NSTates?

This query returns the number of registers that are available for save/recall. As there are ten registers this query always returns ten.

Syntax

MEM → :NST → ?

Example

MEM : NST?

This command queries the number of registers available for save/recall.
The MEMory:STATe Node

This node is used to query and define register names.

The commands associated with this node are:

MEMory:STATe:CATalog?
MEMory:STATe:DEFine
MEMory Subsystem
MEMory:STATe:CATalog?

MEMory:STATe:CATalog?
This query returns a list of the save/recall register names in ascending order of register number. The format of the response is:
<string>,<string>,......,<string>

Syntax

MEM → STAT → CAT → ?

Example

MEM:STAT:CAT?  This command queries the register names.
MEMory:STATe:DEFine <string>,<numeric_value>

This command is used to associate a name with a save/recall register number.

**Syntax**

MEM→:STAT→:DEF→Space→string→numeric_value→

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>A string detailing the register name. A maximum of 12 characters can be used. A to Z (uppercase) a to z (lowercase) 0 - 9 _ (underscore)</td>
<td></td>
</tr>
<tr>
<td>numeric_value</td>
<td>A numeric value (&lt;NR&gt;) for the register number.</td>
<td>0 to 9</td>
</tr>
</tbody>
</table>

**Example**

MEM:STAT:DEF "SETUP1", 4

_This command names register 4 SETUP1._

**Query**

MEMory:STATe:DEFine? <string>

The query returns the register number for the given register name.

**Query Example**

MEM:STAT:DEF? "SETUP1"

_This command queries the register number of SETUP1._
MEMory Subsystem
MEMory:STATe:DEFine <string>,<numeric_value>

Error Messages

If the register number is out of range, error -222, “Data out of range” occurs.

If the name is invalid, error -224, “Illegal parameter value” occurs.

If a register or sensor calibration table with the same name already exists, error -257, “File name error” occurs (command only).
MEMory:TABLE Node

This node is used to define a sensor calibration table and to write to and read data from it.

The commands associated with this node are:

MEMory:TABLE:FREQuency <numeric_value>,<numeric_value>
MEMory:TABLE:FREQuency:POINts?
MEMory:TABLE:GAIN[:MAGnitude]
    <numeric_value>,<numeric_value>
MEMory:TABLE:GAIN[:MAGnitude]:POINts?
MEMory:TABLE:MOVE <string>,<string>
MEMory:TABLE:SELECT <string>
MEMory Subsystem
MEMory:TABLE:FREQuency <numeric_value>{,<numeric_value>}

MEMory:TABLE:FREQuency <numeric_value>{,<numeric_value>}

This command is used to enter frequency data into the current sensor calibration table. Any previous frequency list is cleared before the new frequencies are stored. The frequencies must be entered in ascending order. Entries in the frequency lists correspond as shown with entries in the calibration factor lists. The first calibration factor entered using the MEMory:TABLE:GAIN command is used as the reference calibration factor.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Calibration Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>Reference Calibration Factor</td>
</tr>
<tr>
<td>Frequency 1</td>
<td>Calibration Factor 1</td>
</tr>
<tr>
<td>Frequency 2</td>
<td>Calibration Factor 2</td>
</tr>
<tr>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>Frequency 80</td>
<td>Calibration Factor 80</td>
</tr>
</tbody>
</table>

The number of frequency points must be one less than the number of calibration factor points. This is verified when the sensor calibration table is selected using SENSE:CORRection:CSET:SELECT <string>.

Ensure that the frequency points you use cover the frequency range of the signals that you want to measure. If you measure a signal with a frequency outside the frequency range defined in the sensor calibration table then the power meter uses the highest or lowest point in the sensor calibration table to calculate the calibration factor.

The power meter is capable of storing 20 tables of 80 frequency points.

Syntax

![Syntax diagram](image)

7-22 HP EPM-441A/442A Programming Guide
MEMory Subsystem

MEMory:TABLE:FREQuency <numeric_value>{,<numeric_value>}

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the frequency. The default units are Hz.</td>
<td>1 kHz to 999.9 GHz^1,^2</td>
</tr>
</tbody>
</table>

1. The following measurement units can be used:
   - Hz
   - kHz (10^3)
   - MHz (10^6)
   - GHz (10^9)

2. All frequencies are truncated to a multiple of 1 kHz.

Example

MEM:TABLE:FREQ 200kHz, 600kHz

This command enters frequencies of 200 kHz and 600 kHz into the currently selected sensor calibration table.

Query

MEMory:TABLE:FREQuency?

The query returns a list of frequency points for the sensor calibration table currently selected. The frequencies are returned in Hz.

Query Example

MEM:TABLE:FREQ?

This command queries the frequency points in the currently selected sensor calibration table.

HP EPM-441A/442A Programming Guide 7-23
MEMory Subsystem
MEMory:TABLE:FREQuency <numeric_value>{,<numeric_value>}

Error Messages

If more than 80 frequencies are in the list, error -108, "Parameter not allowed" occurs.

If the frequencies are not entered in ascending order, error -220, "Parameter error;Frequency list must be in ascending order" occurs.

If a sensor calibration table has not been specified using the MEMORY:TABLE:SELection command, the data cannot be entered into the sensor calibration table and error -221, "Settings conflict" occurs.

If a frequency is sent which is outwith the allowed frequency range, error -222, "Data out of range" occurs.
MEMory:TABLE:FREQuency:POINts?

This query returns the number of frequency points for the sensor calibration table currently selected. The response format is `<NRF>`. If no frequency values have been set, this command returns 0. If no sensor calibration table is selected, this command returns `NAN`.

**Syntax**

```
MEM → TABL → FREQ → POIN → ?
```

**Example**

```
MEM:TABL:FREQ:POIN?
```

This command queries the number of frequency points in the current sensor calibration table.
MEMory Subsystem
MEMory:TABLE:GAIN[:MAGNitude] <numeric_value>{,<numeric_value>}

MEMory:TABLE:GAIN[:MAGNitude] <numeric_value>{,<numeric_value>}

This command is used to enter calibration factors into the sensor calibration table currently selected using MEMory:TABLE:SElect. Any previous calibration factor list is cleared before the new calibration factors are stored.

A maximum of 81 parameters can be sent with this command. The first parameter is the reference calibration factor, each subsequent parameter is a calibration factor point in the sensor calibration table.

Entries in the frequency lists correspond as shown with entries in the calibration factor lists.

<table>
<thead>
<tr>
<th>Calibration Factor</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference Calibration Factor</td>
<td>-</td>
</tr>
<tr>
<td>Calibration Factor 1</td>
<td>Frequency 1</td>
</tr>
<tr>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>Calibration Factor 80</td>
<td>Frequency 80</td>
</tr>
</tbody>
</table>

The number of frequency points must be one less than the number of calibration factor data points. This is verified when the sensor calibration table is selected using SENSE:CORRection:CSET:SELECT <string>.

Syntax

```
MEM → :TABL → :GAIN → :MAGN → Space → numeric_value
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the calibration factors. The units are PCT.</td>
<td>1.0 to 150.0</td>
</tr>
</tbody>
</table>
MEMory Subsystem

MEMory:TABLE:GAIN[:MAGNitude] <numeric_value>{,<numeric_value>}

Example

MEM:TABLE:GAIN 97,99.5,97.4

This command enters a reference calibration factor of 97% and calibration factors of 99.5% and 97.4% into the current sensor calibration table.

Query

MEMory:TABLE:GAIN[:MAGNitude]?

The query returns a list of calibration factor points for the currently selected sensor calibration table.

Query Example

MEM:TABLE:GAIN?

This command queries the calibration factors in the current sensor calibration table.

Error Messages

If more than 81 calibration factors are in the list, error -108, "Parameter not allowed" occurs.

If a sensor calibration table is not specified using the MEMory:TABLE:SELECT command, the data cannot be entered and error -221, "Settings conflict" occurs.

If any of the calibration factors are out with the allowed range, error -222, "Data out of range" occurs.
MEMory Subsystem
MEMory:TABLE:GAIN[:MAGNitude]:POINts?

This query is used to return the number of calibration factor points including the reference calibration factor for the currently selected sensor calibration table.

If no values have been sent, 0 is returned. If no sensor calibration table is selected, NaN is returned.

Syntax

MEM → TABL → GAIN → MAGN → POIN → ?

Example

MEM:TABLE:GAIN:POIN?

This command queries the number of calibration points in the current sensor calibration table.
MEMory:TABLE:MOVE <string>,<string>

This command is used to rename a sensor calibration table.

Syntax

```
MEM ➔ TABL ➔ MOVE ➔ Space ➔ string ➔ 1 ➔ string
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>string (1st parameter)</td>
<td>A string containing the existing table name.</td>
<td>existing table name</td>
</tr>
<tr>
<td>string (2nd parameter)</td>
<td>A string detailing the register name. A maximum of 12 characters can be used.</td>
<td>A to Z (uppercase) a to z (lowercase) 0 - 9 _ (underscore)</td>
</tr>
</tbody>
</table>

Example

```
MEM:TABLE:MOVE "tabl","tabl"  This command renames a table named tab1 to tab1a.
```

Error Messages

If either sensor calibration table name is invalid, error -224, “Illegal parameter value” occurs.

If the first parameter does not match an existing table name, error -256, “File name not found” occurs.

If the second parameter matches an existing table name or save/recall register, error -257, “File name error” occurs.
MEMory Subsystem
MEMory:TABLE:SELECT <string>

MEMory:TABLE:SELECT <string>

This command is used to activate a sensor calibration table. A sensor calibration table must be activated before any operation can be performed on it.

Syntax

```
MEM :TABL :SEL string
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>A string detailing the sensor calibration table name. A maximum of 12 characters can be used.</td>
<td>A to Z (uppercase) a to z (lowercase) 0 - 9 _ (underscore)</td>
</tr>
</tbody>
</table>

Example

```
MEM:TABL:SEL "Sensor1"
```

This command selects a sensor calibration table named "Sensor1".

Query

```
MEMory:TABLE:SELECT?
```

The query returns the name of the currently selected sensor calibration table.
OUTput Subsystem
The OUTPut command subsystem is used to switch on and off the POWER REF output.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Parameter Form</th>
<th>Notes</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTPut</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>:ROSCillator</td>
<td>:STATE</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;Boolean&gt;</td>
<td></td>
<td>page 8-3</td>
</tr>
</tbody>
</table>
OUTPut Subsystem
OUTPut:ROSCillator[:STATe] <Boolean>

OUTPut:ROSCillator[:STATe] <Boolean>

This command is used to switch on and off the POWER REF output.

Syntax

```
OUTP ROSC STAT Space 01 OFF
11 ON
```

Example

```
OUTP:ROSC:STAT 1
```

This command switches on the POWER REF output.

Reset Condition

On reset, the POWER REF output is switched off.

Query

```
OUTPut:ROSCillator[:STATe]?
```

The query command enters a 1 or 0 into the output buffer indicating whether or not the POWER REF is switched on.

- 1 is returned when the POWER REF output is switched ON.
- 0 is returned when the POWER REF output is switched OFF.

Query Example

```
OUTP:ROSC?
```

This command queries the status off the POWER REF output.
OUTput Subsystem
OUTPut:ROSCillator[:STATe] <Boolean>
SENSe Subsystem
The SESe command subsystem directly affects device specific settings used to make measurements. The SESe node is optional since this is the primary function of the power meter. The high level command CONFIGure uses the SESe commands to prepare the power meter for making measurements. At a lower level SESe enables you to change the following parameters: RANGE, FREQUENCY, LOSS, CFACTOR | GAIN1 (calibration factor), GAIN2 (channel offset), DCYCLE (duty cycle), and AVERAGE, without completely re-configuring the power meter.

The SESe command subsystem also provides a limit checking function. This function allows you to set the power meter's upper and lower measurement limits. The power meter monitors the power level and indicates when these limits are exceeded.

The SESe command subsystem also allows you to select the measurement speed and the sensor calibration table used for frequency correction.

The numeric suffix of the SESe program mnemonic in the SESe commands refers to a channel, that is SESe1 and SESe2 represent channel A and channel B respectively. If you are using the single channel HP EPM-441A power meter the SESe2 commands are irrelevant and cause the error “Header suffix out of range.”

</tbody>
</table>
This node controls averaging which is used to improve the measurement accuracy. The \texttt{AVERage} subsystem combines successive measurements to produce a new composite result.

The commands associated with this node are:

\begin{verbatim}
[SENSe[1]]|SENSe2:AVERage:COUNT <numeric_value>
[SENSe[1]]|SENSe2:AVERage:COUNT:AUTO <Boolean>
[SENSe[1]]|SENSe2:AVERage[:STATE] <Boolean>
\end{verbatim}
[SENSe[1]]|SENSe2:AVERage:COUNT <numeric_value>

This command is used to enter a value for the filter length. If [SENSe[1]]|SENSe2:AVERage:COUNT:AUTO is set to ON then entering a value for the filter length automatically sets it to OFF. Increasing the value of filter length increases measurement accuracy but also increases the time taken to make a power measurement.

Entering a value using this command automatically turns the [SENSe[1]]|SENSe2:AVERage:STATE command to ON.

Note

For most applications, automatic filter length selection ([SENSe[1]]|SENSe2:AVERage:COUNT:AUTO ON) is the best mode of operation. However, manual filter length selection ([SENSe[1]]|SENSe2:AVERage:COUNT <numeric_value>) is useful in applications requiring either high resolution or fast settling times.

Syntax
SENSe Subsystem  
[SENSE[1]]|SENSe2:AVERage:COUNT <numeric_value>

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value defining the filter length. The default value, DEF, is 4. The value for MIN is 1. The value for MAX is 1024.</td>
<td>1 to 1024(^{1,2}) DEF, MIN, MAX</td>
</tr>
</tbody>
</table>

1. If a numeric value is specified which is not a binary multiple, the power meter rounds the value to the nearest power of 2 within the range allowed. That is 5 is rounded to 4 and 7 is rounded to 8. If the filter length is exactly half way between to powers of two the length is rounded down (that is 6 rounds to 4).
2. In HP 437B remote programming language you cannot enter a value of 1024.

Example

```
AVER:COUNT 400
```

This command enters a filter length of 400 for channel A. The power meter rounds this up to 512.

Reset Condition

On reset, the filter length is set to 4.

Query

```
AVERage:COUNT? [MIN|MAX]
```

The query returns the current setting of the filter length or the values associated with MIN and MAX. The format of the response is <NR1>.

Query Example

```
AVER:COUNT?
```

This command queries the filter length for channel A.

Error Message

If a filter length value is entered using

[SENSE[1]]|SENSe2:AVERage:COUNT while [SENSe[1]]|SENSe2:SPeak is set to 200, the error -221, "Settings Conflict" occurs. However, the filter length value is set but the [SENSe[1]]|SENSe2:AVERage:STATe command is not automatically set ON.

9-6 HP EPM-441A/442A Programming Guide
This command is used to enable and disable automatic averaging. ONCE has no affect on the power meter.

When the auto filter mode is enabled, the power meter automatically sets the number of readings averaged together to satisfy the averaging requirements for most power measurements. The number of readings averaged together depends on the resolution and the power level in which the power meter is currently operating. Figure 9-1 lists the number of readings averaged for each range and resolution when the power meter is in auto filter mode.

Setting this command to ON automatically sets the [SENSe[1]]|SENSe2:AVERage:STATe command to ON.

Figure 9-1: Averaged Readings

<table>
<thead>
<tr>
<th>Minimum Sensor Power</th>
<th>Resolution Setting</th>
<th>Number of Averages</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 dB</td>
<td>1  8  128  128</td>
<td>1  1  8</td>
</tr>
<tr>
<td>10 dB</td>
<td>1  1  16  256</td>
<td>1  1  128</td>
</tr>
<tr>
<td>10 dB</td>
<td>1  1  2  32</td>
<td>1  1  1024</td>
</tr>
<tr>
<td>10 dB</td>
<td>1  1  1  16</td>
<td>1  1  65536</td>
</tr>
</tbody>
</table>

If [SENSe[1]]|SENSe2:AVERage:COUNT:AUTO is set to OFF, the filter length is set by the [SENSe[1]]|SENSe2:AVERage:COUNT command. Using the [SENSe[1]]|SENSe2:AVERage:COUNT command automatically disables automatic averaging.

Auto averaging is enabled by the MEASure:POWer:AC? and CONFIGure:POWer:AC? commands.
SENSe Subsystem

[SENSe[1]]|SENSe2:AVERage:COUNT:AUTO <Boolean>|ONCE

Note
For most applications, automatic filter length selection
([SENSe[1]]|SENSe2:AVERage:COUNT:AUTO ON) is the best
mode of operation. However, manual filter length selection
([SENSe[1]]|SENSe2:AVERage:COUNT <numeric_value>) is
useful in applications requiring either high resolution or fast
settling times.

Syntax

Example

AVER:COUN: AUTO OFF

This command disables
automatic filter length selection for
channel A.

Reset Condition
On reset, automatic averaging is enabled.

Query

[SENSe[1]]|SENSe2:AVERage:COUNT:AUTO?

The query enters a 1 or 0 into the output buffer indicating whether
automatic filter length is enabled or disabled.

- 1 is returned when automatic filter length is enabled.
- 0 is returned when automatic filter length is disabled.

Query Example

AVER:COUN: AUTO?

This command queries whether
automatic filter length selection is
on or off for channel A.

9-8 HP EPM-441A/442A Programming Guide
Error Message

If [SENSe[1]]|SENSe2:AVERage:COUNT:AUTO is set to ON while [SENSe[1]]|SENSe2:SPEED is set to 200, the error -221, “Settings Conflict” occurs. However, automatic averaging is enabled but the [SENSe[1]]|SENSe2:AVERage:STATe command is not automatically set ON.
[SENSe[1]]|SENSe2:AVERage[:STAte] <Boolean>

This command is used to enable and disable averaging.

**Syntax**

![Diagram of syntax](image)

**Example**

```
AVER 1
```

*This command enables averaging on channel A.*

**Reset Condition**

On reset, averaging is enabled.

**Query**

```
[SENSe[1]]|SENSe2:AVERage[:STAte]?
```

The query enters a 1 or 0 into the output buffer indicating the status of averaging.

- 1 is returned when averaging is enabled.
- 0 is returned when averaging is disabled.

**Query Example**

```
SENSe2:AVER?
```

*This command queries whether averaging is on or off for channel B.*

**Error Message**

If [SENSe[1]]|SENSe2:AVERage:STAte is set to ON while [SENSe[1]]|SENSe2:SPEed is set to 200, the error -221, “Settings Conflict” occurs.
[SENSe[1]]|SENSe2:CORRection Node

This node provides for known external losses or gains. These are used to enter duty cycle values, calibration factors and other external gains and losses.

The commands associated with this node are:

[SENSe[1]]|SENSe2:CORRection:CSET[:SELect] <string>
[SENSe[1]]|SENSe2:CORRection:CSET:STATE <Boolean>
[SENSe[1]]|SENSe2:CORRection:DCYcle|GAIN3[:INPUT]
[:MAGNitude] <numeric_value>
[SENSe[1]]|SENSe2:CORRection:DCYcle|GAIN3:STATE <Boolean>
[SENSe[1]]|SENSe2:CORRection:CFACtor|GAIN[1|2][:INPUT]
[:MAGNitude] <numeric_value>
[SENSe[1]]|SENSe2:CORRection:GAIN2:STATE <Boolean>
[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPUT][:MAGNitude]
<numeric_value>
[SENSe[1]]|SENSe2:CORRection:LOSS2:STATE <Boolean>
[SENSe[1]]|SENSe2:CORRection:CSET Node

This node is used to select the active sensor calibration table.

Note
These commands are only relevant with the HP 8480 series power sensors. If any of these commands are used when an HP E-series power sensor is connected the error -241, “Hardware missing” occurs.

The commands associated with this node are:

[SENSe[1]]|SENSe2:CORRection:CSET[:SELect] <string>
[SENSe[1]]|SENSe2:CORRection:CSET:STATe <Boolean>
This command is used to enter the name of the sensor calibration table which is to be used to determine the calibration factors used for frequency correction. The calibration factor is interpolated from the table using the setting for \([\text{SENSe[1]}|\text{SENSe2}}]:\text{FREQuency}\).

Note

If \([\text{SENSe[1]}|\text{SENSe2}}]:\text{CORR}ection:\text{CSET}:\text{STATe is set to OFF, the sensor calibration table is not being used.}\)

Syntax

```
SENS 1\: CORR \: CSET \: SEL \: Space string
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>String data representing a sensor calibration table name.</td>
<td>Any existing table name. (To list names use <code>MEMory:CATalog:TABLE?</code>)</td>
</tr>
</tbody>
</table>

Example

```
CORR:CSET "PW1"
```

This command enters the name of the sensor calibration table which is to be used on channel A.

Reset Condition

On reset the selected table is not affected.
SENSe Subsystem

[SENSe[1]]|SENSe2:CORRection:CSET[:SELection] <string>

**Query**

[SENSe[1]]|SENSe2:CORRection:CSET[:SELection]? 

The name of the sensor calibration table is returned as a quoted string. If no table is selected an empty string is returned.

**Query Example**

CORR:CSET?

*This command queries the sensor calibration table currently used for channel A.*

**Error Messages**

If `<string>` is not valid, error -224, “Illegal parameter value” occurs.

If a sensor calibration table called `<string>` does not exist, error -256, “File name not found” occurs.

When the sensor calibration table is selected, the power meter verifies that the number of calibration points defined is one more than the number of frequency points defined. If this is not the case, error -226, “Lists not the same length” occurs.

If this command is used when an HP E-series power sensor is connected the error -241, “Hardware missing” occurs.
[SENSe[1]]|SENSe2:CORRection:CSET:STATe <Boolean>

This command is used to enable and disable the use of the currently active sensor calibration table. When a sensor calibration table has been selected and enabled, the calibration factors stored in it can be used by specifying the required frequency using the [SENSe[1]]|SENSe2:_FREQUENCY command.

When this command is set to ON, the reference calibration factor is taken from the sensor calibration table and is used during calibration.

**Syntax**

```
SENSE 1 > CORR > CSET > STAT > Space > OFF
   SENSE2
     1 ON
     ?
```

**Example**

`CORR:CSET:STAT 1`  
*This command enables the use of the currently active sensor calibration table for channel A.*

**Reset Condition**

On reset, the sensor calibration table is not affected.

**Query**

`[SENSe[1]]|SENSe2:CORRection:CSET:STATe?`

The query returns a 1 or 0 into the output buffer indicating whether a sensor calibration table is enabled or disabled.

- 1 is returned when the sensor calibration table is enabled.
- 0 is returned when the sensor calibration table is disabled.
SENSe Subsystem
[SENSe[1]]SENSe2:CORRection:CSET:STATe <Boolean>

Query Example

SENSe2:CORR:CSET:STAT?

This command queries whether there is currently an active sensor calibration table for channel B.

Error Message

If you attempt to set this command to ON and no sensor calibration table has been selected using the [SENSe[1]]SENSe2:CORRection:CSET:[SELection] command then error -221, "Settings conflict" occurs and [SENSe[1]]SENSe2:CORRection:CSET:STATe remains OFF.
SENSe Subsystem

[SENSe[1]]|SENSe2:CORRection:DCYClE|GAIN3 Node

[SENSe[1]]|SENSe2:CORRection:DCYClE|GAIN3 Node

This command node controls the pulse power measurement feature of the power meter.

The commands associated with this node are:

[SENSe[1]]|SENSe2:CORRection:DCYClE|GAIN3 [:INPut]
[:MAGNitude] <numeric_value>

[SENSe[1]]|SENSe2:CORRection:DCYClE|GAIN3:STATE <Boolean>

Note

You can use either DCYClE or GAIN3 in these commands, both do the same. Using GAIN3 complies with the SCPI standard whereas DCYClE does not, but may make your program more understandable.
SENSe Subsystem

This command is used to set the duty cycle for the pulse power measurement feature of the power meter. Pulse power measurements average out any aberrations in the pulse such as overshoot or ringing. The result returned for a pulse power measurement is a mathematical representation of the pulse power rather than an actual measurement. The power meter measures the average power in the pulsed input signal and then divides the result by the duty cycle value to obtain a pulse power reading.

Entering a value using this command automatically turns the [SENSe[1]|SENSe2:CORRLection:DCYClE|GAIN3:STATe command to ON.

---

**Note**

Pulse measurements are not recommended using HP E-series power sensors at power levels above -20 dBm.

Pulse power averages out any aberrations in the pulse such as overshooting or ringing. For this reason it is called pulse power and not peak power or peak pulse power.

In order to ensure accurate pulse power readings, the input signal must be pulsed with a rectangular pulse. Other pulse shapes (such as triangle, chirp or Gaussian) will cause erroneous results.

The pulse power on/off ratio must be much greater than the duty cycle ratio.

9-18

HP EPM-441A/442A Programming Guide
SENSe Subsystem

[SENSe[1]]|SENSe2:CORRection:DCYCle:GAIN3[:INPut][:MAGNitude]

Syntax

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the duty cycle. The default value, DEF, is 1%. The value for MIN is 0.001%. The value for MAX is 99.999%. The units are PCT, and are optional.</td>
<td>0.001 to 99.999PCT</td>
</tr>
</tbody>
</table>

Example

CORR:DCYC 90PCT
This command sets a duty cycle of 90% for channel A.

Reset Condition

On reset, the duty cycle is set to 1% (DEF).

Query

[SENSe[1]]|SENSe2:CORRection:DCYCle:GAIN3[:INPut][:MAGNitude]? [MIN|MAX]
The query returns the current setting of the duty cycle or the values associated with MIN and MAX.
SENSe Subsystem
[SENSe[1]]|SENSe2:CORRection:DCYCLE|GAIN3[:iNPut][:MAGNitude]

Query Example

CORR:GAIN3?

This command queries the current setting of the duty cycle for channel A.

Error Messages

If a duty cycle value is entered using
[SENSe[1]]|SENSe2:CORRection:DCYCLE|GAIN3 while
[SENSe[1]]|SENSe2:SPeed is set to 200, the error -221, “Settings Conflict” occurs. However, the duty cycle value is set but the
[SENSe[1]]|SENSe2:CORRection:DCYCLE|GAIN3:STATe command is not automatically set ON.

If this command is used when an HP E-series power sensor is connected, the error -310, “System error; Dty Cyc may impair accuracy with ECP sensor” occurs. If you are using the HP EPM-442A the error message specifies the channel.
[SENSe[1]]|SENSe2:CORRection:DCYClGAIN3:STATe <Boolean>

This command is used to enable and disable the pulse power measurement feature.

The [SENSe[1]]|SENSe2:CORRection:DCYClGAIN3 command should be used to enter the duty cycle of the signal you want to measure.

Syntax

Example

CORR:DCYClSTAT 1

This command enables the pulse measurement feature on channel A.

Reset Condition

On reset, the pulse power measurement feature is disabled.

Query

[SENSe[1]]|SENSe2:CORRection:DCYClGAIN3:STATe?

The query enters a 1 or 0 into the output buffer indicating the status of the pulse power measurement feature.

- 1 is returned when the pulse power measurement feature is enabled.
- 0 is returned when the pulse power measurement feature is disabled.
SENSe Subsystem
[SENSe[1]]|SENSe2:CORRection:DCYClE:GAIN3:STATe <Boolean>

Query Example

CORR:GAIN3:STAT?

This command queries whether the pulse measurement feature is on or off.

Error Messages

If [SENSe[1]]|SENSe2:CORRection:DCYClE:STATus is set to ON while [SENSe[1]]|SENSe2:SPEed is set to 200, the error -221, “Settings Conflict” occurs.

If this command is used when an HP E-series power sensor is connected, the error -310, “System error;Dty Cyc may impair accuracy with ECP sensor” occurs. If you are using the HP EPM-442A the error message specifies the channel.
[SENSe[1]]|SENSe2:CORRection:GAIN[1|2] Node

This node is used to provide a simple correction to the measurement. It is possible to apply two corrections, one for the calibration factor (CFAct or|GAIN1) and one for any other channel offset (GAIN2).

Note

The [SENSe[1]]|SENSe2:CORRection:CFAct or|GAIN1 command can be used for the HP 8480 series power sensors when no sensor calibration table has been set up. If a sensor calibration table is selected the error -221, "Settings Conflict" occurs.

Gain and loss correction are a coupled system. This means that a gain set by [SENSe[1]]|SENSe2:CORRection:GAIN2 is represented in the [SENSe[1]]|SENSe2:CORRection:LOSS2? command. LOSS2 is coupled to GAIN2 by the equation:

\[ \text{Loss} = \frac{1}{\text{Gain}} \]

when the default unit is linear, and

\[ \text{Gain} = -\text{Loss} \]

when the default unit is logarithmic.

The commands associated with this node are:

[SENSe[1]]|SENSe2:CORRection:CFAct or:GAIN[1|2][:INPut][:MAGNitude] <numeric_value>

[SENSe[1]]|SENSe2:CORRection:GAIN2:STATe <Boolean>
SENSe Subsystem

This command is used to enter a value for gain correction. The power meter corrects every measurement by this factor to compensate for the gain.

There are two gains which can be set:

- CFACtor1|GAIN1 is used to enter a gain correction value for the calibration factor.
  You can use either CFACtor or GAIN1 in this command, both do the same. Using GAIN1 complies with the SCPI standard whereas CFACtor does not but may make your program more understandable.

- GAIN2 is used to enter an offset value to compensate for the power meter setup.
  Entering a value for GAIN2 using this command automatically turns the [SENSe[1]|SENSe2:CORRection:GAIN2:STATE command to ON.

Gain and loss correction are a coupled system. This means that a gain set by [SENSe[1]|SENSe2:CORRection:GAIN2 is represented in the [SENSe[1]|SENSe2:CORRection:LOSS2? command.

LOSS2 is coupled to GAIN2 by the equation:

\[
\text{Loss} = \frac{1}{\text{Gain}} \quad \text{when the default unit is linear, and}
\]

\[
\text{Gain} = -\text{Loss} \quad \text{when the default unit is logarithmic.}
\]
Syntax

```
SENS 1 :: CORR .GAIN 1 :: .INP .MAGN
SENS2
:: CFAC
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value (for CFACtor and GAIN1)</td>
<td>A numeric value. The default value, DEF, is 100%. The value for MIN is 1%. The value for MAX is 150%.</td>
<td>1 to 150PCT²</td>
</tr>
<tr>
<td>numeric_value (for GAIN2)</td>
<td>A numeric value. The default value, DEF, is 0.00 dB. The value for MIN is -100 dB. The value for MAX is +100 dB.</td>
<td>-100 to +100 dB</td>
</tr>
</tbody>
</table>

1. For example, a gain of 60% corresponds to a multiplier of 0.6 and a gain of 150% corresponds to a multiplier of 1.5.

Example

```
SENS2:CORR:GAIN2 50
```

This command sets a channel offset of 50 dB for channel B.

Reset Condition

On reset, CFACtor|GAIN1 is set to 100% and GAIN2 to 0.0 dB.
SENSe Subsystem
[SENSe[1]]:SENSe2:CORRection:CFACtor|GAIN[12]|:iNPut[:MAGNitude]

Query
[SENSe[1]]:SENSe2:CORRection:CFACtor|GAIN[12]|:iNPut[:MAGNitude]? [MIN|MAX]

The query returns the current setting of the gain correction or the values associated with MIN and MAX.

If [SENSe[1]]:SENSe2:CORRection:LOSS2 is used to set a gain level, the result of this query is \( \frac{1}{\text{LOSS2}} \) when the default unit is linear, and \(-\text{LOSS2}\) when the default unit is logarithmic.

Query Example

```
CORR:GAIN1?
```

This command queries the current setting of the calibration factor on channel A.

Error Messages

If a channel offset value is entered using [SENSe[1]]:SENSe2:CORRection:GAIN2 while [SENSe[1]]:SENSe2:SPEed is set to 200, the error -221, “Settings Conflict” occurs. However, the channel offset value is set but the [SENSe[1]]:SENSe2:CORRection:GAIN2:STATe command is not automatically set ON.

The SENSe[1]|SENSe2:CORRection:CFACtor|GAIN1 command can be used for the HP 8480 series power sensors when no sensor calibration table has been set up. If a sensor calibration table is selected the error -221, “Settings Conflict” occurs.
SENSe Subsystem

[SENSe[1]]|SENSe2:CORRection:GAIN2:STATe <Boolean>

This command is used to enable and disable a channel offset for the power meter setup. Since GAIN2 and LOSS2 form a coupled system, the command is identical to [SENSe[1]]|SENSe2:CORRection:LOSS2:STATe.

The [SENSe[1]]|SENSe2:CORRection:GAIN2 command should be used to enter the gain value.

Syntax

```
SENSE  1:CORR  :GAIN2 :STAT
SENSE2
```

Example

```
CORR:GAIN2:STAT ON
```

This command enables a channel offset on channel A.

Reset Condition

On reset, channel offsets are disabled.

Query

```
[SENSe[1]]|SENSe2:CORRection:GAIN2:STATe?
```

The query enters 1 or 0 into the output buffer indicating the status of the channel offsets.

- 1 is returned if a channel offset is enabled.
- 0 is returned if a channel offset is disabled.

Query Example

```
CORR:GAIN2:STAT?
```

This command queries whether or not there is a channel offset applied to channel A.
SENSe Subsystem
[SENSe[1]]|SENSe2:CORRction:GAIN2:STATe <Boolean>

Error Message

If [SENSe[1]]|SENSe2:CORRction:GAIN2:STATe is set to ON while [SENSe[1]]|SENSe2:SPEed is set to 200, the error -221, "Settings Conflict" occurs.
[SENSe[1]]|SENSe2:CORRection:LOSS2 Node

This node is used to provide a simple correction to the measurement for an external loss.

Loss and gain correction are a coupled system. This means that a loss set by [SENSe[1]]|SENSe2:CORRection:LOSS2 is represented in [SENSe[1]]|SENSe2:CORRection:GAIN2? command. LOSS2 is coupled to GAIN2 by the equation

\[ \text{Gain} = \frac{1}{\text{Loss}} \] when the default unit is linear, and

\[ \text{Loss} = -\text{Gain} \] when the default is logarithmic.

The commands associated with this node are:

[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPut][:MAGNitude]
<numeric_value>

[SENSe[1]]|SENSe2:CORRection:LOSS2:STATE <Boolean>
SENSe Subsystem
[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPut][:MAGNitude] <numeric_value>

[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPut][:MAGNitude] <numeric_value>

This command is used to enter a channel offset value for the power meter setup, for example cable loss. The power meter then corrects every measurement by this factor to compensate for the loss.

Entering a value for LOSS2 using this command automatically turns the [SENSe[1]]|SENSe2:CORRection:LOSS2:STATe command to ON.

Loss and gain correction are a coupled system. This means that a loss set by [SENSe[1]]|SENSe2:CORRection:LOSS2 is represented in [SENSe[1]]|SENSe2:CORRection:GAIN2? command. LOSS2 is coupled to GAIN2 by the equation

Gain = \( \frac{1}{Loss} \) when the default unit is linear, and

Loss = -Gain when the default is logarithmic.

Syntax

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value. The default value, DEF, is 0.00 dB. The value for MIN is -100 dB. The value for MAX is +100 dB.</td>
<td>-100 to +100 dB</td>
</tr>
</tbody>
</table>

9-30 HP EPM-441A/442A Programming Guide
SENSe Subsystem

[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPut][:MAGNitude] <numeric_value>

Example

CORR:LOSS2 50

This command sets a channel offset of 50 dB for channel A.

Reset Condition

On reset, LOSS2 is set to 0.00 dB.

Query

[SENSe[1]]|SENSe2:CORRection:LOSS2[:INPut][:MAGNitude]? [MIN | MAX]

The query returns the current setting of the channel offset or the values associated with MIN and MAX.

If [SENSe[1]]|SENSe2:CORRection:GAIN2 is used to set a loss level, the result of this query is \( \frac{1}{\text{Gain}^2} \) when the default unit is linear, and \(-\text{Gain}^2\) when the default is logarithmic.

Query Example

CORR:LOSS2?

This command queries the current setting of the channel offset on channel A.

Error Message

If a loss correction value is entered using [SENSe[1]]|SENSe2:CORRection:LOSS2 while [SENSe[1]]|SENSe2:SPEed is set to 200, the error -221, “Settings Conflict” occurs. However, the correction value is set but the [SENSe[1]]|SENSe2:CORRection:LOSS2:STATE command is not automatically set ON.

The SENSe[1]|SENSe2:CORRection:LOSS2 command can be used for the HP 8480 series power sensors when no sensor calibration table has been set up. If a sensor calibration table is selected the error -221, “Settings Conflict” occurs.
SENSe Subsystem
[SENSe[1]]|SENSe2:CORRction:LOSS2:STATe <Boolean>

[SENSe[1]]|SENSe2:CORRction:LOSS2:STATe <Boolean>

This command is used to enable and disable a loss correction for the power meter setup, for example cable loss. Since LOSS2 and GAIN2 form a coupled system, the command is identical to [SENSe[1]]|SENSe2:CORRction:GAIN2:STATe.

The [SENSe[1]]|SENSe2:CORRction:LOSS2:STATe command should be used to enter the loss value.

Syntax

Example

SENSe2:CORR:LOSS2:STAT 1

This command enables loss correction on channel B.

Reset Condition

On reset, loss correction is disabled.

Query

[SENSe[1]]|SENSe2:CORRction:LOSS2:STATe?

The query enters 1 or 0 into the output buffer indicating the status of the loss correction.

• 1 is returned if loss correction is enabled.
• 0 is returned if loss correction is disabled.

Query Example

CORR:LOSS2:STAT?

This command queries whether the loss correction on channel A is on or off.
Error Message

If [SENSe[1]]|SENSe2:CORRection:LOSS2:STATe is set to ON while [SENSe[1]]|SENSe2:SPBed is set to 200, the error -221, "Settings Conflict" occurs.
SENSSe Subsystem
[SENSSe[1]]SENSSe2:FREQuency[:CWl:FIXed] <numeric_value>

This command is used to enter a frequency. If the frequency does not correspond directly to a frequency in the sensor calibration table, the power meter calculates the calibration factor using linear interpolation. For HP 8480 series power sensors the power meter uses linear interpolation to calculate the calibration factor for the frequency entered if [SENSSe[1]]SENSSe2:CORrection:CSET:STATe is ON. For HP E-series power sensors, the calibration factor is calculated using the sensor's calibration factor data held in its EEPROM.

Syntax

![Diagram of the command syntax]

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the frequency. The default value, DEF, is 50 MHz. The value for MIN is 1 kHz. The value for MAX is 999.999 GHz. The default units are HZ.</td>
<td>1 kHz to 999.999 GHz¹</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

¹ The following measurement units can be used:
- Hz
- kHz (10³)
- MHz (10⁶)
- GHz (10⁹)
SENSe Subsystem

\[[\text{SENSe}[1]]\text{SENSe2:}\text{FREQuency[:CW]:F\text{IXed}] <\text{numeric\_value}>\]

Example

\[\text{FREQ 500kHz}\]

This command enters a channel A frequency of 500 kHz.

Reset Condition

On reset, the frequency is set to 50 MHz (DEF).

Query

\[[\text{SENSe}[1]]\text{SENSe2:}\text{FREQuency[:CW]:F\text{IXed}]? \ [\text{MIN}|\text{MAX}]\]

The query returns the current frequency setting or the values associated with MIN and MAX. The units in which the results are returned are Hz.

Query Example

\[\text{SENSe2:FREQ?}\]

This command queries the channel B frequency setting.
SENSe Subsystem
The [SENSe[1]]|SENSe2:LIMit:CLEar Node

The [SENSe[1]]|SENSe2:LIMit:CLEar Node

This node contains the commands that are used to clear any limit failures.

The commands associated with this node are:

[SENSe[1]]|SENSe2:LIMit:CLEar:AUTO <Boolean>|ONCE
[SENSe[1]]|SENSe2:LIMit:CLEar[:IMMediate]
[SENSe[1]]|SENSe2:LIMIT:CLEar:AUTO <Boolean>IONCE

This command is used to control when the FCO (fail counter) is cleared of any limit failures. The FCO is used to determine the results returned by the [SENSe[1]]|SENSe2:LIMIT:FAIL? query.

If **ON** is specified, the FCO is set to 0 each time a measurement:
- is initiated using INITiate[:IMMediate].
- is initiated using INITiate:CONTinuous ON.
- is measured using MEASure?
- is read using READ?

If **OFF** is specified, the FCO is not cleared by the above commands.

If **ONCE** is specified, the FCO is cleared only after the first initialization then starts accumulating any limit failures.

**Syntax**

```
SENSE 1 LIM :CLE AUTO Space 0 OFF
SENSE2
```

**Example**

```
SENSe1:LIM:CLE:AUTO 1
```

*This command switches on automatic clearing of the FCO for channel A.*

**Reset Condition**

On reset, both channels are set to **ON**.
SENSe Subsystem
[SENSe[1]]|SENSe2:LIMIT:CLEAr:AUTO <Boolean>|ONCE

Query

[SENSe[1]]|SENSe2:LIMIT:CLEAr:AUTO?

The query command enters a 1 or 0 into the output buffer indicating whether limit failures are cleared automatically when a new measurement is initiated on the specified channel.

- 1 is entered into the output buffer when limit failures are cleared automatically when a new measurement is initiated.
- 0 is entered into the output buffer when limit failures are not cleared automatically when a new measurement is initiated.

In the case where limit failures are cleared once, when a query occurs a 1 is entered into the output buffer if no measurement is initiated. If a measurement is initiated then 0 is entered.

Query Example

SENSe1:LIMIT:CLEAr:AUTO?  This command queries when the FCO is cleared for channel A.
[SENSe[1]]|SENSe2:LImites:CLEar[:IMMediate]

This command is used to immediately clear the FCO (fail counter) of any limit failures for the specified channel. The FCO is used to determine the results returned by the [SENSe[1]]|SENSe2:LImites:FAIL? query.

Syntax

Example

SENSe2:LImites:CLEar:IMMediate

This command clears the FCO for channel B.
SENSe Subsystem

[SENSe[1]][SENSe2]:LIMit:FAIL?

[SENSe[1]][SENSe2]:LIMit:FAIL?

This query enters a 1 or 0 into the output buffer indicating whether there have been any limit failures for the specified channel. A limit failure is defined as [SENSe[1]][SENSe2]:LIMit:FCO? being non-zero. The FCO (fail counter) can be zeroed using the [SENSe[1]][SENSe2]:LIMit:CLEar command.

- 1 is returned when one or more limit failures have occurred.
- 0 is returned when no limit failures have occurred.

Syntax

Example

SENSe1:LIM:FAIL?  

This command queries if there have been any limit failures on channel A.

Reset Condition

On reset, the buffer is set to zero for both channels.
[SENSe[1]]|SENSe2:LIMIT:FCOnt?

This query is used to return the total number of limit failures for the specified channel.

If the appropriate STATE commands are set to ON, each time a measurement is initiated on the specified channel and the measurement result is outside the limits, the counter is incremented by one.

If the measured value is equal to a limit, this is a limit pass.

The counter is reset to zero by any of the following commands:

- "*RST"
- [SENSe[1]]|SENSe2:LIMIT:CLEar:IMMediate
- [SENSe[1]]|SENSe2:LIMIT:CLEar:AUTO ON

When [SENSe[1]]|SENSe2:LIMIT:CLEar:AUTO is set to ON, the counter is set to zero each time a measurement:

- is measured using MEASure?
- is read using READ?
- is initiated using:
  - INITiate[:IMMediate] or,
  - INITiate:CONTInuous ON.

When [SENSe[1]]|SENSe2:LIMIT:CLEar:AUTO is set to ONCE, the counter is set to zero the first time a measurement:

- is measured using MEASure?
- is read using READ?
- is initiated using:
  - INITiate[:IMMediate] or,
  - INITiate:CONTInuous ON.

The maximum number of errors is 2^{16}-1. If more than 2^{16}-1 errors are detected the counter returns to zero.
Syntax

Example

This command queries the number of limit failures on channel A.

Reset Condition

On reset, the counter is set to zero on both channels.
This command is used to enter a value for the lower test limit for the specified channel used in the \texttt{[SENSe[1]]|SENSe2:LIMIT:LOWER[:DATA]} test. The value is entered in dBm. When the measured power is less than the value specified in \texttt{[SENSe[1]]|SENSe2:LIMIT:LOWER[:DATA]}, \texttt{[SENSe[1]]|SENSe2:LIMIT:FAIL?} reports a fail. When the measured power is greater than or equal to the limit, a fail is not reported.

### Syntax

```
SENS 1 LIM :LOW :DATA
```

### Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value. The default value, DEF, is -90.00 dBm. The value for MIN is -150 dBm. The value for MAX is +230 dBm.</td>
<td>-150 to +230 dBm</td>
</tr>
</tbody>
</table>

### Example

```
SENS2:LIM:LOW:DATA MIN
```

This command enters a lower limit for channel B of -150 dBm.
SENSe Subsystem

[SENSe[1]]|SENSe2:LIMit:LOWer[:DATA] <numeric_value>

Reset Condition

On reset, both channels are set to -90.00 dBm (DEF).

Query

[SENSe[1]]|SENSe2:LIMit:LOWer[:DATA]? [MIN|MAX]

The query returns the current setting of the lower limit or the values associated with MIN and MAX for the specified channel.

Query Example

SENSe2:LIM:LOW:DATA?  This command queries the lower limit set for channel B.
[SENSe[1]]|SENSe2:LIMIT:STATE <Boolean>

This command is used to enable and disable the test limits for the specified channel.

Syntax

Example

SENSe2:LIMIT:STATE 1

This command enables the limit checking function for channel B.

Reset Condition

On reset, limit checking is disabled.

Query

[SENSe[1]]|SENSe2:LIMIT:STATE?

The query enters 1 or 0 into the output buffer indicating the status of the limits testing feature for the specified channel.

- 1 is returned when limits testing is enabled.
- 0 is returned when limits testing is disabled.

Query Example

SENSe1:LIMIT:STATE?

This command queries whether the limit checking function for the channel A is on or off.

Error Message

If [SENSe[1]]|SENSe2:LIMIT:STATE is set to ON while [SENSe[1]]|SENSe2:SPeed is set to 200, the error -221, "Settings Conflict" occurs.
SENSe Subsystem

[SENSe[1]]|SENSe2:LIMit:UPPer[:DATA] <numeric_value>

This command is used to enter a value for the upper test limit for the specified channel used in the [SENSe[1]]|SENSe2:LIMit:FAIL? test. The value is entered in dBm. When the measured power is greater than the value specified in [SENSe[1]]|SENSe2:LIMit:UPPer[:DATA], [SENSe[1]]|SENSe2:LIMit:FAIL? reports a fail. When the measured power is less than or equal to the limit, a fail is not reported.

Syntax

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value. The default value, DEF, is +90.00 dBm. The value for MIN is -150 dBm. The value for MAX is +230 dBm.</td>
<td>-150 to +230 dBm</td>
</tr>
</tbody>
</table>

Example

SEN2:LIM:UPP:DATA -20dBM

This command enters an upper limit of -20 dBm for channel B.

Reset Condition

On reset, both channels are set to +90.00 dBm (DEF).
SENSe Subsystem

[SENSe[1]]|SENSe2:LIMIT:UPPer[:DATA] <numeric_value>

Query

[SENSe[1]]|SENSe2:LIMIT:UPPer[:DATA]? [MIN|MAX]

The query returns the current setting of the upper limit or the values associated with MIN and MAX for the specified channel.

Query Example

SENSe2:LIM:UPP:DATA?  This command queries the setting of the upper limit for channel B.
SENSe Subsystem

[SENSe[1]] | SENSe2:POWer:AC:RANGE <numeric_value>

This command is used with the HP E-series power sensors to select one of two power ranges.

- If 0 is selected, the power sensor’s lower range is selected.
- If 1 is selected, the power sensor’s upper range is selected.

Setting a range with this command automatically switches [SENSe[1]] | SENSe2:POWer:AC:RANGE:AUTO to OFF.

Syntax

```
SEN S 1 \rightarrow POW \rightarrow :AC \rightarrow :RANG \rightarrow \text{Space} \rightarrow \text{numeric_value} \rightarrow ?
```

Example

```
POW:AC:RANGE 0
```

This command sets the power sensor to its lower range.

Reset Condition

On reset, the upper range is selected.

Query

```
[SENSe[1]] | SENSe2:POWer:AC:RANGE?
```

The query enters a 1 or 0 into the output buffer indicating the status of the power sensor’s range.

- 1 is returned when the upper range is selected.
- 0 is returned when the lower range is selected.

Query Example

```
POW:AC:RANG?
```

This command queries the current setting of the power sensor range.

Error Message

This command is used with the HP E-series power sensors. If one is not connected, the error -241, “Hardware missing” occurs.
This command is used with the HP E-series power sensors to enable and disable autoranging. When autoranging is ON, the power meter selects the best measuring range for the measurement. When autoranging is set to OFF, the power meter remains in the currently set range.

If `INITiate:CONTInuous` is set to ON and `TRIGger:SOURce` is set to `IMMEDIATE`, the range will track the input power if `[SENSe[1]] | SENSE2:POWER:AC:RANGE:AUTO` is ON.

If the power meter is not making measurements then autoranging only occurs when the power meter is triggered.

**Syntax**

```
SENSE 1:POW.AC:RANG:AUTO SPACE 0 OFF 1 ON
```

**Example**

`POW:AC:RANG:AUTO 0`  
*This command disables autoranging.*

**Reset Condition**

On reset, autoranging is enabled.

**Query**

`[SENSe[1]] | SENSE2:POWER:AC:RANGE:AUTO?`

The query enters a 1 or 0 into the output buffer indicating the status of autoranging.

- 1 is returned when autoranging is enabled.
- 0 is returned when autoranging is disabled.
SENSe Subsystem
[SENSe[1]]SENSe2:POWer:AC:RANGe:AUTO <Boolean>

Query Example

POW: AC: RANG: AUTO?

This command queries whether auto ranging is on or off.

Error Message

If this command is set to OFF when there is not an HP E-series power sensor connected, the error, -241, "Hardware missing" occurs.
This command is used to select the measurement speed on the selected channel. The speeds available are 20, 40 and 200 readings/second. Refer to “Getting the Best Speed Performance”, on page 1-54 for further information.

When a channel is set to 200 readings/second the following couplings occur.

<table>
<thead>
<tr>
<th>Command</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>[SENSe[1]]</td>
<td>SENSe2:AVERAGE:STATE</td>
</tr>
<tr>
<td>[SENSe[1]]</td>
<td>SENSe2:LIMIT:STATE</td>
</tr>
<tr>
<td>[SENSe[1]]</td>
<td>SENSe2:CORREction:DCycle:STATE</td>
</tr>
<tr>
<td>[SENSe[1]]</td>
<td>SENSe2:CORREction:GAIN2:STATE</td>
</tr>
<tr>
<td>CALCulate[1</td>
<td>2]:GAIN:STATE</td>
</tr>
<tr>
<td>CALCulate[1</td>
<td>2]:RELative:STATE</td>
</tr>
<tr>
<td>CALCulate1:MATH:EXPression</td>
<td>&quot;(SENSe1)&quot;</td>
</tr>
<tr>
<td>CALCulate2:MATH:EXPression</td>
<td>&quot;(SENSe2)&quot;</td>
</tr>
</tbody>
</table>

1. This change only occurs on the channel specified in the SENSe:SPeed command. When the specified channel is changed from 200 readings/second to either 20 or 40 readings/second the settings that were in place when 200 readings/second mode was entered are restored.

2. This change occurs when either channel is set to 200 readings/second. When both channels are changed from 200 readings/second to either 20 or 40 readings/second the settings that were in place when 200 readings/second mode was entered are restored.

Syntax

```
SENSE 1 : SPE Space numeric_value
```

HP EPM-441A/442A Programming Guide 9-51
SENSe Subsystem

[SENSe[1]]|SENSe2:SPEed <numeric_value>

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the measurement speed. The default is 20.</td>
<td>20, 40, 200</td>
</tr>
</tbody>
</table>

Example

SPE 40

This command sets the channel A speed to 40 readings/second.

Reset Condition

On reset, the speed is set to 20 readings/second.

Query

[SENSe[1]]|SENSe2:SPEed?

The query returns the current speed setting, either 20, 40 or 200.

Query Example

SPE?

This command queries the current speed setting for channel A.

Error Message

If <speed> is not 20, 40 or 200, error -224, “Illegal parameter value” occurs.

If an HP E-series power sensor is not connected and the <numeric_value> is set to 200 readings/second the error -241, “Hardware missing” occurs.
STATus Subsystem
The **STATus** command subsystem enables you to examine the status of the power meter by monitoring the “Device Status Register”, “Operation Status Register” and the “Questionable Status Register”.

Table 10-1 summarizes the effects of various commands and events on the status data structures in the power meter.

**Table 10-1: Status Data Structure**

<table>
<thead>
<tr>
<th>Status Data Structure</th>
<th>*RST</th>
<th>*CLS</th>
<th>Power On</th>
<th>STATus: PRESet</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCPI Transition Filters</td>
<td>none</td>
<td>none</td>
<td>preset</td>
<td>preset</td>
</tr>
<tr>
<td>SCPI Enable Registers</td>
<td>none</td>
<td>none</td>
<td>preset</td>
<td>preset</td>
</tr>
<tr>
<td>SCPI Event Registers</td>
<td>none</td>
<td>clear</td>
<td>clear</td>
<td>none</td>
</tr>
<tr>
<td>SCPI Error/Event Queue enable</td>
<td>none</td>
<td>none</td>
<td>preset</td>
<td>preset</td>

<tr>
<td>SCPI Error/Event Queue</td>
<td>none</td>
<td>clear</td>
<td>clear</td>
<td>none</td>
</tr>
<tr>
<td>IEEE488.2 Registers ESE SRE</td>
<td>none</td>
<td>none</td>
<td>clear</td>
<td>none</td>
</tr>
<tr>
<td>IEEE488.2 Registers SESR STB</td>
<td>none</td>
<td>clear</td>
<td>clear</td>
<td>none</td>
</tr>
</tbody>
</table>
As the status reporting commands are orthogonal, the same commands apply to all the registers. The registers are:

- STATus:DEViCe (page 10-8)
- STATus:OPERation (page 10-11)
- STATus:OPERation:CALibrating[:SUMMary] (page 10-12)
- STATus:OPERation:LLFail[:SUMMary] (page 10-13)
- STATus:OPERation:MEASuring[:SUMMary] (page 10-14)
- STATus:OPERation:SENSe[:SUMMary] (page 10-15)
- STATus:OPERation:TRIGger[:SUMMary] (page 10-16)
- STATus:OPERation:ULFail[:SUMMary] (page 10-17)
- STATus:QUESTionable (page 10-20)
- STATus:QUESTionable:CALibration[:SUMMary] (page 10-21)
- STATus:QUESTionable:POWer[:SUMMary] (page 10-22)

The following five commands operate on each of these registers. However, to avoid duplication they are only listed once.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Parameter Form</th>
<th>Notes</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>:CONDITION?</td>
<td>&lt;NRf&gt;</td>
<td>&lt;non-decimal numeric&gt;</td>
<td>[query only]</td>
</tr>
<tr>
<td>:ENABLE</td>
<td>&lt;NRf&gt;</td>
<td>&lt;non-decimal numeric&gt;</td>
<td>[query only]</td>
</tr>
<tr>
<td>[:EVENT?]</td>
<td>&lt;NRf&gt;</td>
<td>&lt;non-decimal numeric&gt;</td>
<td></td>
</tr>
<tr>
<td>:NTRansition</td>
<td>&lt;NRf&gt;</td>
<td>&lt;non-decimal numeric&gt;</td>
<td></td>
</tr>
<tr>
<td>:PTRansition</td>
<td>&lt;NRf&gt;</td>
<td>&lt;non-decimal numeric&gt;</td>
<td></td>
</tr>
</tbody>
</table>

For example, to use the :CONDITION? command on the STATus:DEViCe register, use:

```
STATus:DEViCe:CONDITION?
```

To use the :NTRansition command on the STATus:OPERation:SENSe[:SUMMary] register, use:

```
STATus:OPERation:SENSe[:SUMMary]:NTRansition
```
Status Register Set Commands

The following descriptions detail the five commands which can be applied to all the SCPI registers. These commands should be prefixed with the node or nodes that represent the SCPI Register Set you require to control. For example, to use the :ENABLE command on the STATUS:QUESTIONable register use STATUS:QUESTIONable:ENABLE.

The five Status Register Set commands are:

:CONDition?
:ENABLE <NRf>|<non-decimal numeric>
[:EVENT?]?
:NTTransition <NRf>|<non-decimal numeric>
:PTTransition <NRf>|<non-decimal numeric>

:CONDition?

This query returns a 16 bit decimal-weighted number representing the bits set in the Condition Register of the SCPI Register Set you require to control. The format of the return is <NR1> in the range of 0 to 32767 (2^{15}-1). The contents of the Condition Register remain unchanged after it is read.

Syntax

[:EVENT]?

This query returns a 16 bit decimal-weighted number representing the bits set in the Event Register of the SCPI Register Set you require to control. The format of the return is <NR1> in the range of 0 to 32767 (2^{15}-1). This query clears all bits in the register to 0.

Syntax
:ENABLE <NRf><non-decimal numeric>

This command is used to set the Enable Register of the particular SCPI Register Set you require to control. The parameter value, when rounded to an integer and expressed in base 2 has its first 15 bits written into the Enable Register of the SCPI Register Set concerned. The last bit (bit 15) is always set to 0.

Syntax

Parameters

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRf</td>
<td>The value used to set the Enable Register.</td>
<td>0 to $2^{16}-1$</td>
</tr>
<tr>
<td>non-decimal numeric</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Query

:ENABLE?

The query returns a 15 bit decimal-weighted number representing the contents of the Enable Register of the SCPI Register Set being queried. The format of the return is $<\text{NRf}>$ in the range of 0 to 32767 ($2^{15}-1$).
STATUs Subsystem
Status Register Set Commands

:NTRansition <NRf>|<non-decimal numeric>

This command is used to set the Negative Transition Register of the SCPI Register Set you require to control. The parameter value, when rounded to an integer and expressed in base 2 has its first 15 bits written into the Negative Transition Register of the SCPI Register Set concerned. The last bit (bit 15) is always set to 0.

Refer to “Status Reporting”, on page 1-59 for a general description of the status register model.

Syntax

```
... :NTR space NRf non-decimal numeric ...
```

Parameters

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRf</td>
<td>The value used to set the NTR Register.</td>
<td>0 to 2^{16}.1</td>
</tr>
<tr>
<td>non-decimal numeric</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Query

:NTRansition?

The query returns a 15 bit decimal-weighted number representing the contents of the Negative Transition Register of the SCPI register set being queried. The format of the return is <NR1> in the range of 0 to 32767 (2^{15}.1).
:PTRansition <NRF><non-decimal numeric>

This command is used to set the Positive Transition Register of the SCPI Register Set you require to control. The first 15 bits of the input parameter are written into the Positive Transition Register of the SCPI Register Set concerned. The last bit (bit 15) is always set to 0.

Refer to “Status Reporting”, on page 1-59 for a general description of the status register model.

Syntax

```
:PTR space NRF

non-decimal numeric

? 
```

Parameters

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRF</td>
<td>The value used to set the PTR Register.</td>
<td>0 to $2^{16}-1$</td>
</tr>
<tr>
<td>non-decimal numeric</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Query

:PTRansition?

The query returns a 15 bit decimal-weighted number representing the contents of the Positive Transition Register of the SCPI register set being queried. The format of the return is <NRF> in the range of 0 to 32767 ($2^{15}-1$).
Device Status Register Sets

The following registers contain information which give device status information. The contents of the individual registers of these register sets may be accessed by appending the commands listed in “Status Register Set Commands”.

The following command descriptions detail the SCPI register you require to control but do not detail the Register Set commands.

The one Device Status Register Set is:

STATus:DEvice:

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A sensor connected</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B sensor connected (HP EPM-442A only)</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>Channel A sensor error</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>Channel B sensor error (HP EPM-442A only)</td>
</tr>
<tr>
<td>5</td>
<td>32</td>
<td>Channel A sensor Front/Rear</td>
</tr>
<tr>
<td>6</td>
<td>64</td>
<td>Channel B sensor Front/Rear (HP EPM-442A only)</td>
</tr>
<tr>
<td>7-15</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>14</td>
<td>16384</td>
<td>Front Panel key press</td>
</tr>
<tr>
<td>15</td>
<td>-</td>
<td>Bit 15 always 0</td>
</tr>
</tbody>
</table>
The Channel A and B sensor connected bits (bits 1 and 2), when queried with the STATus:DEvice:CONDition? query are set to:
- 1, when a power sensor is connected.
- 0, when no power sensor is connected.

The Channel A and B sensor connected bits (bits 1 and 2), when queried with the STATus:DEvice:Event? query indicate whether a power sensor has been connected or disconnected depending on the state of the corresponding bits of STATus:DEvice:NTransition and STATus:DEvice:PTRansition. If the corresponding bit in:
- STATus:DEvice:NTransition is 1, then
- STATus:DEvice:PTRansition is 1, then

The Channel A and B sensor error bits (3 and 4) are set to:
- 1, if the HP E-series power sensor EEPROM has failed or if there are power sensors connected to both the rear and front panel connectors.
- 0, for every other condition.

The Channel A and B sensor Front/Rear bits (bits 5 and 6) are set to:
- 1, if the power sensor is connected to the rear panel.
- 0, if the power sensor is connected to the front panel.

The Front Panel key press bit (bit 14), when queried with the STATus:DEvice:Event? query indicates whether any front panel keys have been pressed since power up or since you last queried the device status register. Note, this bit ignores the :NTRansition, and :PTRansition registers, and a:CONDition? query always returns a 0.
Operation Register Sets

The following registers contain information which is part of the power meters normal operation. The contents of the individual registers of these register sets may be accessed by appending the commands listed in "Status Register Set Commands".

The following command descriptions detail the SCPI register you require to control but do not detail the Register Set commands.

The seven Operation Register Sets are:

STATUS:OPERation
STATUS:OPERation:CALibrating[:SUMMarY]
STATUS:OPERation:LPLFail[:SUMMarY]
STATUS:OPERation:MEASuring[:SUMMarY]
STATUS:OPERation:SENSe[:SUMMarY]
STATUS:OPERation:TRIGger[:SUMMarY]
STATUS:OPERation:ULFail[:SUMMarY]
The operation status register set contains conditions which are a part of the operation of the power meter as a whole.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>CALibrating Summary</td>
</tr>
<tr>
<td>1 - 3</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>MEASuring Summary</td>
</tr>
<tr>
<td>5</td>
<td>32</td>
<td>Waiting for TRIGger Summary</td>
</tr>
<tr>
<td>6 - 9</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>10</td>
<td>1024</td>
<td>SENSE Summary</td>
</tr>
<tr>
<td>11</td>
<td>2048</td>
<td>Lower Limit Fail Summary</td>
</tr>
<tr>
<td>12</td>
<td>4096</td>
<td>Upper Limit Fail Summary</td>
</tr>
<tr>
<td>13 to 15</td>
<td>-</td>
<td>Not used (bit 15 always 0)</td>
</tr>
</tbody>
</table>

These bits are set and cleared under the conditions shown on page 1-74.

**Syntax**

```
STAT> :OPER
```
STATus Subsystem
STATus:OPERation:CALibrating[:SUMMary]

STATus:OPERation:CALibrating[:SUMMary]
The operation status calibrating summary register set contains information on the calibrating status of the power meter.
The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A CALibrating Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B CALibrating Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set at the beginning of zeroing (CALibration:ZERO:AUTO ONCE) and at the beginning of calibration (CALibration:AUTO ONCE). Also for the compound command/query CALibration[:ALL]?, this bit is set at the beginning of the calibration sequence.

These bits are cleared at the end of zeroing or calibration.

Syntax

```
(STAT)→:OPER→:CAL→:SUMM→
```
The operation status lower limit fail summary register set contains information on the lower limit fail status of the power meter.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A LLFail Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B LLFail Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set if a power measurement is made and the lower limit test fails.

These bits are cleared if a power measurement is made and the test is enabled and passes.

Syntax

```
STAT:OPER:LLF:SUMM
```
STATus Subsystem
STATus:OPERation:MEASuring[:SUMMary]

STATus:OPERation:MEASuring[:SUMMary]

The operation status measuring summary register set contains information on the measuring status of the power meter.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A MEASuring Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B MEASuring Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set when the power meter is taking a measurement.

These bits are cleared when the measurement is finished.

Syntax

```
STAT :OPER :MEAS :SUMM
```
STATus:OPERation:SENSe[:SUMM]ary

The operation status sense summary register set contains information on the status of the power sensors.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A SENSe Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B SENSe Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set when the power meter is reading data from the HP E-series power sensor EEPROM.

These bits are cleared when the power meter is not reading data from the HP E-series power sensor EEPROM.

Syntax

```
STAT→:OPER→(SENSe)→:SUMM
```
STATus Subsystem
STATus:OPERation:TRIGger[:SUMMary]

STATus:OPERation:TRIGger[:SUMMary]
The operation status trigger summary register set contains information on the trigger status of the power meter.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A TRIGger Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B TRIGger Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set when the power meter enters the “wait for trigger” state. Refer to Figure 1-7, “Trigger System,” on page 1-51.

These bits are cleared when the power meter enters the “idle” state. Refer to Figure 1-7, “Trigger System,” on page 1-51.

Syntax

```
STAT→:OPER→:TRIG→:SUMM→
```
The operation status upper limit fail summary register set contains information on the upper limit fail status of the power meter.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A ULFail Status</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B ULFail Status (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set if a power measurement is made and the upper limit test fails.

These bits are cleared if a power measurement is made and the test is enabled and passes.

Syntax

```
STAT→:OPER→:ULF→:SUMM→
```
STATus Subsystem

**STATus:PRESet**

**PRESet** sets a number of the status registers to their preset values as shown below - all other registers are unaffected. Bit 15 is always 0.

<table>
<thead>
<tr>
<th>Register</th>
<th>Filter/Enable</th>
<th>PRESet Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPERational</td>
<td>ENABle</td>
<td>all zeros</td>
</tr>
<tr>
<td></td>

<tr>
<td>QUESTionable</td>
<td>ENABle</td>
<td>all zeros</td>
</tr>
<tr>
<td></td>
<td>PTR</td>
<td>all ones</td>
</tr>
<tr>
<td></td>
<td>NTR</td>
<td>all zeros</td>
</tr>
<tr>
<td>All Others</td>
<td>ENABle</td>
<td>all ones</td>
</tr>
<tr>
<td></td>
<td>PTR</td>
<td>all ones</td>
</tr>
<tr>
<td></td>
<td>NTR</td>
<td>all zeros</td>
</tr>
</tbody>
</table>

**Syntax**

```
STAT---:PRESet
```
Questionable Register Sets

The Questionable Register Sets contain information which gives an indication of the quality of the data produced by the power meter. The contents of the individual registers in these register sets may be accessed by appending the commands listed in "Status Register Set Commands".

The following command descriptions detail the SCPI register you require to control but do not detail the Register Set commands.

The three Questionable Register Sets are:

STATUS:QUESTIONable
STATUS:QUESTIONable:CALibration[:SUMMARY]
STATUS:QUESTIONable:POWer[:SUMMARY]
STATus Subsystem
STATus:QUESTIONable

STATus:QUESTIONable

The questionable register set contains bits which give an indication of the quality of various aspects of signals processed by the power meter as a whole.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 2</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>POWER Summary</td>
</tr>
<tr>
<td>4 to 7</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>8</td>
<td>256</td>
<td>CALibration Summary</td>
</tr>
<tr>
<td>9</td>
<td>512</td>
<td>Power On Self Test</td>
</tr>
<tr>
<td>10 to 15</td>
<td>-</td>
<td>Not Used (bit 15 always 0)</td>
</tr>
</tbody>
</table>

Bit 3 is set by the logical OR outputs of the STATus:QUESTIONable:POWER:SUMMARY register set.

Bit 8 is set by the logical OR outputs of the STATus:QUESTIONable:CALibration:SUMMARY register set.

Bit 9 is set if power-on self-test fails, and cleared if it passes.

Syntax

```
(STAT)\rightarrow\text{:QUES}\rightarrow
```
The questionable calibration summary register set contains bits which give an indication of the quality of the data produced by the power meter due to its calibration status.

The following bits in these registers are used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Summary of Channel A CALibration</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Summary of Channel B CALibration (HP EPM-442A only)</td>
</tr>
<tr>
<td>3-15</td>
<td>-</td>
<td>Not used</td>
</tr>
</tbody>
</table>

These bits are set by the following:

- Error -231, “Data questionable; CH\<A\>|\<B\>:ZERO ERROR”
- Error -231, “Data questionable; CAL ERROR”
- Error -231, “Data questionable; CAL ERROR ChA”
- Error -231, “Data questionable; CAL ERROR ChB”

These bits are cleared when any of the three commands listed above succeed and no errors are placed on the error queue.

Syntax

```
STAT → QUES → CAL → SUMM
```
The questionable power summary register set contain bits which give an indication of the quality of the power data being acquired by the power meter.

The following bits in these registers shall be used by the power meter:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Decimal Weight</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>Not used</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Channel A Power</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Channel B Power (HP EPM-442A only)</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>Upper Window Power</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>Lower Window Power</td>
</tr>
<tr>
<td>5</td>
<td>32</td>
<td>Channel A Please Zero</td>
</tr>
<tr>
<td>6</td>
<td>64</td>
<td>Channel B Please Zero (HP EPM-442A only)</td>
</tr>
</tbody>
</table>

Bit 1 is set when any of the following errors occur:

- Error -230, “Data corrupt or stale”
- Error -231, “Data questionable; Input Overload” (HP EPM-441A only)
- Error -231, “Data questionable; Input Overload ChA” (HP EPM-442A only)

Bit 2 is set when any of the following errors occur:

- Error -230, “Data corrupt or stale”
- Error -231, “Data questionable; Input Overload ChB” (HP EPM-442A only)

Bits 3 is set when the following error occurs:

- Error -231, “Data questionable; Upper window log error”

Bit 4 is set when the following error occurs:

- Error -231, “Data questionable; Lower window log error”
Bit 5 is set when the following condition occurs:

- Channel A requires zeroing

Bit 6 is set when the following condition occurs (HP EPM-442A only):

- Channel B requires zeroing

These bits are cleared when no errors or events are detected by the power meter during a measurement covering the causes given for it to set.

**Syntax**

```
STAT→:QUES→:POW→:SUMM→
```
STATus Subsystem
STATus:QUESTionable:POWer[SUMMary]
SYSTem Subsystem
The **SYSTEM** command subsystem is used to return error numbers and messages from the power meter, preset the power meter, set the GPIB address, set the command language and query the SCPI version.

<table>
<thead>
<tr>

</tbody>
</table>
SYSTem:COMMunicate:GPIB[:SELF]:ADDReSS <numeric_value>

This command sets the GPIB address of the power meter.

Syntax

```
SYST<COMM>GPIBS<SELF>ADDR Space numeric_value
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_value</td>
<td>A numeric value for the address. The default value, DEF, is 13. The value for MIN is 0. The value for MAX is 30.</td>
<td>0 to 30 DEF MIN MAX</td>
</tr>
</tbody>
</table>

Example

```
SYST:COMM:GPIB:ADDR 13
```

This command sets the GPIB address to 13.

Query

```
SYSTem:COMMunicate:GPIB[:SELF]:ADDReSS? MIN|MAX
```

The query returns the current setting of the GPIB address or the values associated with MIN and MAX.

Query Example

```
SYST:COMM:GPIB:ADDR?
```

This command queries the setting of the GPIB address.
SYSTem Subsystem
SYSTem:ERRor?

SYSTem:ERRor?

This query returns error numbers and messages from the power meter's error queue. When an error is generated by the power meter, it stores an error number and corresponding message in the error queue. One error is removed from the error queue each time the SYSTem:ERRor? command is executed. The errors are cleared in the order of first-in first-out, that is, the oldest errors are cleared first. To clear all the errors from the error queue, execute the *CLS command. When the error queue is empty, subsequent SYSTem:ERRor? queries return a +0, "No error" message. The error queue has a maximum capacity of 30 errors.

For further information on individual error messages refer to the User's Guide.

Syntax

SYS\text{\textdagger}T \rightarrow \text{ERR} \rightarrow ?

Example

SYS\text{\textdagger}T:ERR? \quad \text{This command queries the oldest error message stored in the power meter's error queue.}

Reset Condition

On reset, the error queue is unaffected.

Error Messages

The error queue has a maximum capacity of 30 errors. If the queue overflows, the last error is replaced with -350, "Queue overflow". No additional errors are accepted by the queue until space becomes available.
**SYSTem:LANGuage <character_data>**

This command is used to change the remote programming language accepted by the power meter from SCPI to the HP 437B programming language. To return to using the SCPI programming language when in the HP 437B mode use the SYST:LANG SCPI command. After sending the command to change language wait 100 ms before sending any other commands. When changing between languages the power meter is placed into local mode. It is recommended that the instrument is preset following a language switch.

**Syntax**

```
SYST:LANG character_data
```

**Parameters**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_data</td>
<td>Character data containing the programming language.</td>
<td>HP437B SCPI</td>
</tr>
</tbody>
</table>

**Example**

```
SYST:LANG HP437B
```

*This command sets the power meter to perform using the HP 437B programming language.*

**Query**

```
SYSTem:LANGuage?
```

The query returns the current setting of the remote programming language.

**Query Example**

```
SYST:LANG?
```

*This command queries the setting of the remote programming language.*
SYSTem:PRESet

This command is used to preset the power meter. The result of this command is similar to the *RST command. Refer to Table 11-1 for more information about the preset configuration.

Note

All settings apply to both *RST and to SYSTem:PREset unless stated otherwise.

Syntax

\[ \text{SYST} \rightarrow \text{PRES} \rightarrow \]

Example

\[ \text{SYST:PRE} \]

This command presets the power meter.

Table 11-1: Preset Settings

SYSTem:VERSi0n?

This query returns the version of SCPI used in the power meter. The response is in the form of XXXX.Y, where XXXX is the year and Y is the version number.

Syntax

SYST\rightarrow(VERS)\rightarrow?  

Example

SYST:VERS?  

This command queries which version of SCPI is used in the power meter.
SYStem Subsystem
SYStem:VERSion?
TRIGger Subsystem
TRIGger Subsystem

The TRIGger subsystem is used to synchronize device actions with events.

The TRIGger subsystem includes the ABORT, INITiate and TRIGger commands. These are all at the root level in the command hierarchy but they are grouped here because of their close functional relationship.

<table>
<thead>
<tr>

</tr>
<tr>
<td>:SOURCE</td>
<td></td>
<td></td>
<td>page 12-12</td>
</tr>
</tbody>
</table>

Further information on triggering is detailed in “Triggering the Power Meter”, on page 1-49.

The numeric suffix of the TRIGger program mnemonic in the TRIGger commands refers to a channel, that is TRIGger1 and TRIGger2 represent channel A and channel B respectively. If you are using the single channel HP EPM-441A power meter the TRIGger2 commands are irrelevant and cause the error “Header suffix out of range.”
The ABORT command removes the specified channel from the "wait-for-trigger" state and places it in the "idle" state. It does not affect any other settings of the trigger system. When the INITiate command is sent, the trigger system responds as it did before ABORT was executed.

If INITiate:CONTInuous is ON, then after ABORT the specified channel immediately goes into the "wait-for-trigger" state.

Syntax

Example

This command places channel A in the "idle" state.
TRIGger Subsystem

INITiate Node

INITiate Node

This command node allows you to place the power meter in the "wait-for-trigger" state.

The INITiate commands are overlapped, that is, the power meter can continue parsing and executing subsequent commands while initiated. Refer to IEEE 488.2, section 12 for further details. Note that the pending operation flag is set when the power meter moves out of the "idle" state and is cleared when it re-enters the "idle" state.

The commands associated with this node are:

INITiate[1|2][:IMMediate]
INITiate[1|2]:CONTInuous <Boolean>
INITiate[1|2]:CONTinuous <Boolean>

This command is used to set the power meter for either a single trigger cycle or continuous trigger cycles. A trigger cycle means that the power meter exits the “wait-for-trigger” state and starts a measurement. When entering local mode, INITiate:CONTinuous is set to ON.

If INITiate:CONTinuous is set to:

- OFF, the trigger system remains in the “idle” state until it is set to ON, or INITiate:IMMediate is received. Once this trigger cycle is complete the trigger system returns to the “idle” state.
- ON, the trigger system is initiated and exits the “idle” state. On completion of each trigger cycle, the trigger system immediately commences another trigger cycle without entering the “idle” state.

Syntax

```
INIT  =>  1  =>  CONT  =>  Space  =>  0  =>  OFF
        =>  2
```

Example

```
INIT2:CONT ON
```

This command places channel B in the “wait-for-trigger” state.

Reset Condition

On reset (*RST), this command is disabled.

On preset (SYSTEM:PRESet) and instrument power-up, this command is enabled.

Query

```
INITiate[1|2]:CONTinuous?
```

The query enters a 1 or 0 into the output buffer.

- 1 is returned when there is continuous triggering.
- 0 is returned when there is only a single trigger.
TRIGger Subsystem
INITiate[1|2]:CONTinuous <Boolean>

Query Example

INIT2:CONT?

This command queries whether channel B is set for single or continuous triggering.
INITiate[1|2][:IMMediate]

This command is used to place the power meter in the "wait-for-trigger" state. When a trigger is received, the measurement is taken and the result placed in the power meter memory. If TRIGger:SOURce is set to IMMEDIATE the measurement begins as soon as INITiate:IMMediate is executed.

Use FETCH? to transfer a measurement from memory to the output buffer. Refer to "FETCH[1 | 2] Queries", on page 2-21 for further details.

**Syntax**

![Diagram](attachment:image)

**Example**

```
INIT2:IMM
```

This command places channel B in the "wait-for-trigger" state.

**Error Messages**

If the power meter is not in the "idle" state or INITiate:CONTinuous is ON, error -213, "INIT ignored" occurs.
TRIGGER Subsystem

TRIGGER Node

This node controls the behavior of the trigger system.

The commands associated with this node are:

TRIGGER[1|2]:DELAY:AUTO <Boolean>
TRIGGER[1|2]:IMMEDIATE
TRIGGER[1|2]:SOURCE BUS|IMMEDIATE|HOLD
**TRIGger[1|2]:DELay:AUTO <Boolean>**

This command is used to determine whether or not there is a settling-time delay before a measurement is made.

When this command is set to:

- **ON**, the power meter inserts a settling-time delay before taking the requested measurement. This settling time allows the internal digital filter to be updated with new values to produce valid, accurate measurement results. The trigger with delay command allows settling time for the internal amplifiers and filters. It does not allow time for power sensor delay.

In cases of large power changes, the delay may not be sufficient for complete settling. Accurate readings can be assured by taking two successive measurements for comparison.

- **OFF**, the power meter makes the measurement immediately a trigger is received.

**TRIGger[1|2]:DELay:AUTO is ignored if TRIGger[1|2]:IMMediate is set to ON.**

**Syntax**

```
TRIG 1.0 AUTO Space 01OFF
    2 11ON
```

**Example**

```
TRIG:DEL:AUTO ON
```

*This command enables a delay on channel A.*

**Reset Condition**

On reset, **TRIGger:DELay:AUTO** is set to **ON**.
TRIGger Subsystem
TRIGger[112]:DE Lay:AU TO <Boolean>

Query

TRIGger:DE Lay:AU TO?

The query enters a 1 or 0 into the output buffer indicating the status of TRIGger:DE Lay:AU TO.

- 1 is returned when it is ON.
- 0 is returned when it is OFF.
TRIGger[1|2][:IMMEDIATE]

This command causes a trigger to occur immediately, provided the specified channel is in the “wait-for-trigger” state. When this command is executed, the measurement result is stored in the power meter’s memory. Use FETCH? to place the measurement result in the output buffer.

TRIGger[1|2]:DELAY:AUTO is ignored if TRIGger[1|2][:IMMEDIATE] is set to ON.

Syntax

Example

TRIG

This command causes a channel A trigger to occur immediately.

Error Messages

If the power meter is not in the “wait-for-trigger” state, then TRIGger:IMMEDIATE causes error -211, “Trigger ignored”.

HP EPM-441A/442A Programming Guide 12-11
TRIGGER subsystem
TRIGGER[12]:SOURCE BUS IMMEDIATE HOLD

TRIGGER[12]:SOURCE BUS IMMEDIATE HOLD

This command configures the trigger system to respond to the specified source. This command only selects the trigger source. You should use the INITiate command to place the power meter in the "wait-for-trigger" state. The following trigger sources are available:

- **BUS**
  The trigger source is the group execute trigger <GET> bus command, a *TRG common command or the TRIGGER IMMEDIATE SCPI command.

- **HOLD**
  Triggering is suspended. The only way to trigger the power meter is to use the TRIGGER IMMEDIATE.

- **IMMEDIATE**
  The trigger system is always true.
  If INITiate:CONTInuous is ON the power meter is continuously triggering (free run mode).
  If an INITiate:IMMEDIATE command is sent a measurement is triggered then the power meter returns to the idle state.

On instrument power-up and when entering local mode, the trigger source is set to IMMEDIATE.

**Note**

The MEASURE, READ? and CONFIGURE commands automatically set the trigger source to IMMEDIATE.
The READ? or MEASURE commands should not be used if the trigger source is BUS or HOLD.

**Syntax**

```
TRIG 1 SOUR 2 SPACE BUS IMM IMM HOLD
```

12-12 HP EPM-441A/442A Programming Guide
Example

TRIG:SOUR IMM

*This command configure channel A for immediate triggering.*

Reset Condition

On reset, the trigger source is set to IMMEDIATE.

Query

TRIGger:SOURce?

The query returns the current trigger source, either IMM, BUS or HOLD.

Query Example

TRIG:SOUR?

*This command queries channel A's trigger source.*
TRIGger Subsystem
TRIGger[12]:SOURce BUSIMMEDIATE,HOLD
UNIT Subsystem
UNIT Subsystem

UNIT Subsystem

The UNIT command subsystem is used to set the power meter measurement units to Watts and % (linear) or dBm and dB (logarithmic).

The numeric suffix of the UNIT program mnemonic in the UNIT commands refers to a window, that is UNIT1 and UNIT2 represent the upper and lower windows respectively.

The UNIT:POWER and UNIT:POWER:RATIo commands are coupled, that is, if:

- UNIT:POWER is set to dBm then UNIT:POWER:RATIo is dB.
- UNIT:POWER is set to W then UNIT:POWER:RATIo is %.

13-2

HP EPM-441A/442A Programming Guide
UNIT[12]:POWer <amplitude_unit>

This command is used to set the selected window's measurement units. For any command which accepts a numeric value in more than one unit and the power suffix is omitted then the units set by UNIT:POWer are used.

For the HP EPM-441A:

- UNIT1:POWer sets the power measurement units for the upper window. In addition, it also sets the power suffix for any SENSE1 command that requires but omits the power suffix.
- UNIT2:POWer sets the power measurement units for the lower window.

For the HP EPM-442A:

- UNIT1:POWer sets the power measurement units for the upper window. In addition, it also sets the power suffix for any SENSE1 command that requires but omits the power suffix.
- UNIT2:POWer sets the power measurement units for the lower window. In addition, it also sets the power suffix for any SENSE2 command that requires but omits the power suffix.

For ratio and relative power measurements, if UNIT:POWer is

- W, the measurement units are percentage.
- DBM, the measurement units are dB relative.

**Syntax**

```
UNIT 1:POW Space amplitude_unit
```

HP EPM-441A/442A Programming Guide 13-3
UNIT Subsystem
UNIT[1|2]:POWer <amplitude_unit>

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>amplitude_unit</td>
<td>The measurement unit. The default unit is dBm.</td>
<td>W DBM</td>
</tr>
</tbody>
</table>

Example

UNIT1:POW DBM

This command sets the measurement units for the upper window and the default units for any relevant SENSE1 command to dBm.

Reset Condition

On reset, both channels are set to dBm.
UNIT Subsystem
UNIT[1|2]:POWer <amplitude_unit>

Query

UNIT[1|2]:POWer?

The query returns the current setting of the measurement units.

Query Example

UNIT2:POW?

This command queries which measurement units are being used on the lower window. In addition, for the HP EPM-442A this command also queries the default units for any relevant SENSe2 command.
UNIT Subsystem
UNIT[12]:POW:RATio <ratio_unit>

UNIT[12]:POW:RATio <ratio_unit>

This command is used on the HP EPM-442A to set the default units used when inputting and outputting power ratio data.

- UNIT1:POW:RATio sets the ratio measurement units for the upper window. In addition, it also sets the ratio suffix for any SENSE1 command that requires but omits the ratio suffix.
- UNIT2:POW:RATio sets the ratio measurement units for the lower window. In addition, it also sets the ratio suffix for any SENSE2 command that requires but omits the ratio suffix.

Syntax

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio_unit</td>
<td>The ratio measurement unit. The default unit is dB.</td>
<td>DB, PCT</td>
</tr>
</tbody>
</table>

Example

UNIT1:POW:RAT DB

This command sets the ratio measurement units for the upper window and the default units for any relevant SENSE1 command to dB.

Reset Condition

On reset, the units are set to dB.
UNIT Subsystem
UNIT[1|2]:POWer:RATio <ratio_unit>

Query
UNIT[1|2]:POWer:RATio?
The query returns the current setting of the ratio measurement units.

Query Example
UNIT2:POW:RAT?

This command queries which ratio measurement units are being used on the lower window. It also queries the default units for any relevant SENSE2 command.

Error Message
If this command is used with an HP EPM-441A, error -113, "Undefined header" occurs.
UNIT Subsystem
UNIT[112]:POWer:RATio <ratio_unit>
IEEE488.2 Command Reference
IEEE-488 Compliance Information

This chapter contains information about the IEEE 488.2 Common (*) Commands that the power meter supports. It also describes the universal command statements which form the nucleus of HP-IB programming; they are understood by all instruments in the network. When combined with programming language codes, they provide all management and data communication instructions for the system.

The command descriptions are in alphabetical order.

**IEEE-488.2 Common Commands**

*CLS  Clear Status  page 14-7
*DDT  Define Device Trigger  page 14-8
*DDT? Define Device Trigger  page 14-8
*ESE  Event Status Enable  page 14-10
*ESE? Event Status Enable  page 14-10
*ESR? Event Status Register  page 14-11
*IDN? Identify  page 14-12
*OPC  Operation Complete  page 14-13
*OPC? Operation Complete  page 14-13
*OPT? Options  page 14-14
*RCL  Recall  page 14-15
*RST  Reset  page 14-16
*SAV  Save  page 14-17
*SRE  Service Request Enable  page 14-18
*SRE? Service Request Enable  page 14-18
*STB? Status Byte  page 14-20
*TRG  Trigger  page 14-22
*TST? Test  page 14-23
*WAI  Wait  page 14-24
Universal Commands

DCL

The DCL (Device Clear) command causes all HP-IB instruments, or addressed instruments, to assume a cleared condition. The definition of device clear is unique for each instrument. For the power meter:

- All pending operations are halted, that is, *OPC? and *WAI.
- The parser (the software that interprets the programming codes) is reset and now expects to receive the first character of a programming code.
- The output buffer is cleared.

For further information refer to “Using Device Clear to Halt Measurements”, on page 1-81.

GET

The GET (Group Execute Trigger) command triggers all channels that are in the “wait-for-trigger” state.

Using the *DDT command may change the function of the GET command.

Error Message

If TRIGger:SOURce is not set to BUS then error -211, “Trigger ignored” occurs.

If the power meter is not in the “wait-for-trigger” state then error -211, “Trigger ignored” occurs.

GTL

The GTL (Go To Local) command is the complement to remote. It causes the power meter to return to local control with a fully enabled front panel. When reverting to local mode the power meter triggering is set to free run.
LLO

The LLO (Local Lock Out) command can be used to disable the front panel local key. With this key disabled, only the controller (or a hard reset by the line power switch) can restore local control.

PPC

When addressed to listen, the PPC (Parallel Poll Configure) command will cause the power meter to be configured according to the parallel poll enable secondary command which should follow this command.

PPD

Sending the PPC command followed by the PPD (Parallel Poll Disable) command will disable the power meter from responding to a parallel poll. This is effectively a selective disable.

<table>
<thead>

</tbody>
</table>

PPE

Once the power meter has received a PPC command, the PPE (Parallel Poll Enable) secondary command configures the power meter to respond to a parallel poll on a particular data line with a particular level.
### Table 14-2: PPE Mapping

<td>7</td>
<td>128</td>
<td>Always 0</td>
</tr>
</tbody>
</table>

### PPU

The PPU (Parallel Poll Unconfigure) command disables the power meter from responding to a parallel poll. This is effectively a universal disable.

### SDC

The SDC (Selected Device Clear) command causes all HP-IB instruments in the listen state, to assume a cleared condition. The definition of a selected device clear is unique for each instrument. For the power meter:

- All pending operations are halted, that is, *OPC? and *WAI.*
- The parser (the software that interprets the programming codes) is reset and now expects to receive the first character of a programming code.
- The output buffer is cleared.
IEEE488.2 Command Reference
Universal Commands

SPD

The SPD (Serial Poll Disable) command terminates the serial poll mode for the power meter and returns it to its normal talker state where device dependent data is returned rather than the status byte.

SPE

The SPE (Serial Poll Enable) command establishes the serial poll mode for the power meter. When the power meter is addressed to talk, a single eight bit status byte is returned (refer to “The Status Byte”, on page 1-69 for further information).
*CLS

The *CLS (CLear Status) command clears the status data structures. The SCPI registers (Questionable Status, Operation Status and all the other SCPI registers), the Standard Event Status Register, the Status Byte, and the Error/Event Queue are all cleared.

Syntax

*CLS
`*DDT <arbitrary block program data> | <string program data>`

The `*DDT` (Define Device Trigger) command determines the power meter's response to a `GET` (Group Execute Trigger) message or `*TRG` common command. This command effectively turns `GET` and `*TRG` into queries, with the measured power being returned.

**Syntax**

```
*DDT [arbitrary block program data] [string program data]
```

**Parameters**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>arbitrary block</td>
<td>The command which is executed on a <code>GET</code> or <code>*TRG</code>.</td>
<td><code>#nN&lt;action&gt;^1,2</code></td>
</tr>
<tr>
<td>program data</td>
<td></td>
<td></td>
</tr>
<tr>
<td>string program data</td>
<td></td>
<td><code>&lt;action&gt;^1</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. The `<action>` field of the parameter may contain:
   - `FETC?`
   - `FETC1?`
   - `FETC2?` (HP EPM-442A only)
   - `*TRG`
   - `TRIG1`
   - `TRIG2` (HP EPM-442A only)

2. The first digit after the # indicates the number of following digits. The following digits indicate the length of the data.

Examples of `<arbitrary block program data>` parameters are:

- `#15FETC?` and `#206FETC?`

Examples of `<string program data>` are:

- `"FETC1?", "FETC?" and "TRIG1;FETC1"`

**Reset Condition**

On reset, the `<action>` field of `*DDT` is set to `*TRG`. 
Query

*DDT?

The query returns the action which is performed on receipt of a GET or +TRG. This is returned as a <definite length arbitrary block response data> value which is in the form of #nN<action> as described on page 14-8.

Error Message

If an invalid parameter is received error -224, “Illegal parameter value” occurs.
The **ESE (Event Status Enable) <NRf>** command sets the Standard Event Status Enable Register. This register contains a mask value for the bits to be enabled in the Standard Event Status Register. A 1 in the Enable Register enables the corresponding bit in the Status Register; a 0 disables the bit. The parameter value, when rounded to an integer and expressed in base 2, represents the bit values of the Standard Event Status Enable Register. Table 14-3 shows the contents of this register.

**Table 14-3: *ESE Mapping***

<table>
<thead>

</tr>
</tbody>
</table>

**Syntax**

```
*ESE <NRf> <Space> ?
```

**Parameters**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRf</td>
<td>A value used to set the Standard Event Status Enable Register.</td>
<td>0 to 255</td>
</tr>
</tbody>
</table>

**Query**

```
*ESE?
```

The query returns the current contents of the Standard Event Status Enable Register. The format of the return is <NR> in the range of 0 to 255.
*ESR?

The *ESR? query returns the contents of the Standard Event Status Register then clears it. The format of the return is <NR1> in the range of 0 to 255. Table 14-4 shows the contents of this register.

Table 14-4: *ESR? Mapping

<table>
<thead>
<tr>
<th>Bit</th>

</tr>
<tr>
<td>6</td>
<td>64</td>
<td>Not used</td>
</tr>
<tr>
<td>7</td>
<td>128</td>
<td>Power On</td>
</tr>
</tbody>
</table>

Syntax

*ESR → ?
The *IDN? query allows the power meter to identify itself. The string returned will be either:

HEWLETT-PACKARD,EPM-441A,<serial number>,A1.XX.YY
HEWLETT-PACKARD,EPM-442A,<serial number>,A2.XX.YY
HEWLETT-PACKARD,437B,,2.0

where:

- <serial number> uniquely identifies each power meter.
- A1.XX.YY and A2.XX.YY represents the firmware revision with XX and YY representing the major and minor revisions respectively.

Syntax

```
*IDN → ?
```
**OPC**

The *OPC* (OPeration Complete) command causes the power meter to set the operation complete bit in the Standard Event Status Register when all pending device operations have completed.

**Syntax**

```
*OPC
```

**Query**

```
*OPC?
```

The query places an ASCII 1 in the output queue when all pending device operations have completed.
"OPT?"

The "OPT?" query reports the options installed in the power meter and returns:

"" empty string for a standard instrument
"002" for an option 002 instrument
"003" for an option 003 instrument

Syntax

```
*OPT?  ?
```
The *RCL <NRf> (ReCaLi) command restores the state of the power meter from the specified save/recall register. An instrument setup must have been stored previously in the specified register.

Syntax

```
*RCL → Space → NRf
```

Parameters

<table>
<thead>
<tr>
<th>Type</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRf</td>
<td>The number of the register to be recalled.</td>
<td>1 to 10</td>
</tr>
</tbody>
</table>

Error Message

If the register does not contain a saved state error -224, "Illegal parameter value" occurs.
IEEE488.2 Command Reference

*RST

The *RST (ReSeT) command places the power meter in a known state. The power meter is reset to the state shown in Table 11-1 on page 11-6.

Syntax

*RST
**SAV <NRf>**

The *SAV <NRf>* (SAVe) command stores the current state of the power meter in the specified register.

Syntax

```
*SAV  Space  NRf
```

Parameters

<table>
<thead>
<tr>
<th>Item</th>
<th>Description/Default</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRf</td>
<td>The number of the register that the current state of the power meter is to be saved to.</td>
<td>1 to 10</td>
</tr>
</tbody>
</table>
The *SRE <NRF> command sets the Service Request Enable register bits. This register contains a mask value for the bits to be enabled in the Status Byte Register. A 1 in the Enable Register enables the corresponding bit in the Status Byte Register; a 0 disables the bit. The parameter value, when rounded to an integer and expressed in base 2, represents the bits 0 to 5 and bit 7 of the Service Request Enable Register. Bit 6 is always 0. Table 14-5 shows the contents of this register. Refer to the pullout at the end of chapter 1 for further information.

</tr>
</thead>
<tbody>
<tr>
<td>NRF</td>
<td>A value used to set the Service Request Enable Register.</td>
<td>0 to 255</td>
</tr>
</tbody>
</table>
Query

*SRE?

The query returns the contents of bits 0 to 5 and bit 7 of the Service Request Enable Register. The format of the return is <NR1> in the ranges of 0 to 63 or 128 to 191 (that is, bit 6 is always 0).
The *STB? (Status Byte) query returns bit 0 to 5 and bit 7 of the power meter's status byte and returns the Master Summary Status (MSS) as bit 6. The MSS is the inclusive OR of the bitwise combination (excluding bit 6) of the Status Byte and the Service Request Enable registers. The format of the return is <NR1> in the ranges of 0 to 255. Table 14-6 shows the contents of this register. Refer to the pullout at the end of chapter 1 for further information.

|     |        | 1 - An OPERation status condition has occurred |
IEEE 488.2 Command Reference

`*STB?`

Syntax

`*STB` → `?`
*TRG

The *TRG (TRiGger) command triggers all channels that are in the “wait-for-trigger” state. It has the same effect as Group Execute Trigger (GET).

Using the *DDT command may change the function of the *TRG command.

Syntax

*TRG

Error Message

If TRIGger:SOURce is not set to BUS then error -211, “Trigger ignored” occurs.

If the power meter is not in the “wait-for-trigger” state then error -211, “Trigger ignored” occurs.
The *TST? (TeST) query causes the power meter to perform the HP-IB self test which takes approximately 30 seconds. The HP-IB self test consists of the following tests:

- ROM checksum
- RAM
- Battery
- Display Assembly
- Calibrator
- Measurement Assembly
- Communications Assembly (Implicit)

The result of the test is placed in the output queue.

- 0 is returned if the test passes.
- 1 if the test fails.

**Syntax**

```
*TST? ?
```
The *WAI (WAIt) command causes the power meter to wait until either:

- all pending operations are complete,
- the device clear command is received,
- power is cycled,

before executing any subsequent commands or queries.

Syntax

```
*WAI
```
